From the laborious Multi-tasking discussion which has been going on here, it sounds like there may be quite a few. You're more familiar with marketing software than I, so I wouldn't hazard to suggest a price for the developers' kit. But I would caution you from pricing yourself out of the market. What good is the kernel, if there is no software to run with it?

It looks like you may indeed have the right approach. I've admired your work in the past. I hope you get enough replies to start up your idea!

1057. Does FOLDRXXX _really_ work w/new ROMS?

Newsgroup: comp.sys.atari.st
Date: 1988-01-08 03:44:02 UTC
From: schuster@dasys1.UUCP
Message-ID: <2484@dasys1.UUCP>
Source record: 255157

Recently some articles were posted by Atari folks (I forgot who - perhaps it was Allan Pratt) as well as Landon Dyer, in which it was asserted that FOLDRXXX.PRG will work properly with ALL versions of TOS - past, present, and future.

Last week on CompuServe's Atari Developer's Forum, Dave Small said that some of Data Pacific's hard drives were acting "40-folder-ish" once connected to a Mega, while they were fine when running on an older machine. The version of FOLDRXXX.PRG they are using was the "official" one posted to CIS, GEnie, etc. (I'm not even sure there exists more than one version).

This brings me back to GEMBOOT. The most recent version I have (v1.10) came with a utility program to find and display the address of the GEM memory block nodelist (GEMFRL) as well as display all the allocated memory blocks. The docs state that in the "old" roms GEMFRL was located at $56FA and if this location is no longer valid, the GEMBOOT environment must be changed to reflect the actual location of GEMFRL.

Running this program under the new (04/22/87) roms gives a location of $7E9C, and GEMBOOT does indeed enlarge the number of type 4 (directory cache) memory blocks when so configured.

Next I looked at FOLDRXXX.PRG. The discussion on CIS said that it contained a look-up table of ROM version dates. Within the program the following information (re-formatted, of course) appears:
$4E75 11/20/1985
$56FA 02/06/1986
$56FA 04/24/1986
$56FA 06/01/1986
$7E0A 00/00/0000
(actually the last "date" might not be an entry at all, as the table is padded at the end with nulls).

This table brings forth two very alarming impressions!
1. The system date of the current roms, 04/11/1987, is NOWHERE IN THIS TABLE.
2. The address of $7E0A, which I take it is a projection of where GEMFRL might be in the future, is WRONG. The TOS header lists GEMFRL at $7E9C.

Just for fun, I zapped the last "entry" to read:
$7E9C 04/22/1987
rebooted my system, and re-ran GEMFRL.TOS. The number of type 4 blocks allocated had increased by 50%!

Granted a lot of the above information may be shaky, reverse-engineered, or based upon other people's mistaken "facts". Still, it raises questions about the point-blank assertion that FOLDRXXX.PRG was designed to work with ANY

POSSIBLE version of TOS. Would an Atari spokesperson care to post a COMPLETE, AUTHORITATIVE answer?

This reminds me of a joke. . .

A guy goes to a doctor and says "Doc, it hurts when I do this" (he lifts
an arm up, or something)

So the doctor says, "well then, don't do that".

If running marble-madness slows up a compile too much, don't run
marble-madness.

The moral of the story is, don't ask us do be limited by others "limitations".
As opposed to IBM, and now even (Cr)Apple, who are now bending down to the
lowest common denominator, who don't want to burden the average user with
unnecessary complexity (the original closed-Mac architecture was a
manifestation of this philosophy).

> I may want to collaborate with.

I think Wade is right on target here. Multi-tasking does not have to be seen
by the user to be important. On the Amiga, you can't HELP but use multi-
tasking, because the operating system is using it all the time. Each disk
drive has a separate "Filing System" process running (use MonProc, you'll see
them), there is a separate input task running (I believe that Intuition really
is an input handler, so technically, it runs as part of the input device task),
each CLI window has a console task associated with it, the serial port has a
separate task controlling it.

Why is this important? Because it makes it so much easier to do things. For example, early on in the Amiga's life, Matt Dillon (I think) distributed a set of asynchronous file routines. These are very useful, and almost trivial to implement under a multi-tasking OS (not to belittle Matt's work - it's quite good).

Or how about the Workbench? Contrary to many people's belief, the WB is NOT the operating system. It's just a program. A plain, old, ordinary program, with no special tricks or hooks. An ordinary mortal could write a program that does similar actions. Witness HackBench. I've often thought about writing a WB replacement myself.

If you want to talk about disk swapping, try switching between applications on a Macintosh. It has to load the Finder every time. Why do you think theres a "mini-finder" menu option? I keep trying to pull down the "screen" and use the finder which I expect to still be running back there.

I've written programs that monitor other programs (MonProc and MonIDCMP), and that run as input handlers (ClickUpFront, HeliosMouse, wKeys), and some stuff that I haven't released. These would be much more difficult without multi-tasking.

Code can be made much more modular with multi-tasking, and smaller, too. Unix people should love this, because you can make programs much more like filters, except you have both ends of the pipe running at the same time, passing data via a message port, or even a PIPE: device. Functions don't have to be duplicated from program to program. For instance, if I write a program that graphs a function, I will not have to add a save-to-IFF-file option, because I already have a program that lets me select a portion of a window or screen and save it as an IFF file. That's a normal program - no special desk-accessory hooks, no special requirements about what programs I can use it with, or what ones I HAVE to have running when I use it.

Don't get me wrong, desk-accessories are great (I'd never be able to use a Mac without them), but they are an attempt to achieve multi-taksing where it's not built into the system to start with. Admirable! Great stuff! Keep up the good work! But don't complain when someone offers you what you've been trying to achieve all along.

> THE POINT IS THIS: As a programmer I find the idea of writing
> such a program as being much simpler with multi-tasking facilities
> than without them.

Exactly! Right on!

> My question for you is, what do you have against multi-tasking?

I also wonder the same thing. Where's the beef?

> Take OUR (all of us who have given testomonials) word for it that
> the disk swapping "nightmare" is indeed just a bad dream.

As I mentioned before, I'd hate to have to load the Workbench in from disk every time I quit using a program! I'm much happier letting it run in the background until I need it again.

One last comment: (finally :-) the times I find multi-tasking the most
helpful is when I WASN'T expecting to have to use it. If I'm using a word
processor writing a paper, and need to check some results, I can just start up
my statistical analysis program to get my answers (and I can keep on writing
while it loads in of the floppy). I don't want to have to know ahead of time
that I need to start up whatever carousel or special multi-tasking editor
I need in order to do this. If I knew ahead of time, I'd have done the
statistics before I started the word-processor!

Well, I've gone on far too long as it is. Thanks for listening.

re: bugs in bms package -

i've been running a bms-based hard disk system since last january.
the only bugs i have ever encountered were software bugs. recall that
the bms adapter board has a battery-backed clock. it seems that chris
rhodin, the guy who runs bms and does the development, made a very small
but important error in the clock-setting program (settime.prg, i think -
the one that goes in your auto folder) which screwed up on february.
actually it was kind of humorous. never affected hard disk use at all.
he found the problem feb. 1 1987, and had updated software out in the mail
to everyone shortly thereafter.

i'm mainly posting this to stop what could be a harmful rumor. i am a
very satisfied customer of berkeley microsystems. their product is
reasonably priced, in my opinion, and their telephone support is superb
(of course, before they had any documentation, it had to be! :-)

the bms-100 adapter has evolved somewhat; it is supposedly laid out more
attractively on the board, it is pretty well documented, the software has
all been rewritten. it's a pretty mature product now.

if there were hardware bugs, i would be interested in hearing about them.
if not, please don't do bms any disservice by spreading such rumors.

one more note: i wrote an article for ST Applications magazine last spring
detailing the construction of a bms-based hard disk system for the ST.
it covers all the details of a single-HD system, and vaguely addresses

the double-HD system too (at that time i only had one HD). it appeared
in march 87, i think. at that time i offered to mail out copies, in
either electronic or paper form, to anyone who requested one. that
offer still stands. note that the electronic form omits the graphics
(done on my cad system at work, not on the st), so if you want the whole
thing you should buy the magazine or request the paper copy from me.
if you want electronic, mail me at the address below; if you want paper,
send me a self-addressed stamped envelope to the postal address below.

Tony:

I tried several times to reach you via e-mail, but was unsuccessful (not surprising since the path was 17 machines long). There is a programm called STSPEECH that will speak a line typed in on the keyboard or speak an already-created text file. Needless to say, it has a very strong "synthesized speech" accent but it really quite understandable. It is a public domain program. Send me e-mail if you want the details.

>
>lineaterlineaterlineaterlineater
>
>
> Does anyone have the document file on how to hook up an IBM
>style drive?

Josh;

Here is the connections that I made. Has been doen to the Tandons and others without problems.

ST pin # IBM Style drive pin #

1 ---------- 30
2 ---------- 32
3 ---------- 3
4 ---------- 8
5 -- This is the drive select - hook to #2 (B) on IBM Style
6 -- Drive select also, but ignore this one
7 ---------- 3

8 ---------------------- 16
9 ---------------------- 18
10 ---------------------- 20
11 ---------------------- 22
12 ---------------------- 24
13 ---------------------- 26
14 ---------------------- 28

There is also a resistor that will have to be pulled up, to make
the drive work correctly. I Think it's R49 on most. It's value is in the
range of 100 to three hundred Ohm's. It's usually situated close to the
drive select block in the IBM Style drive.

A little more info here.

On the Atari's drive connector, pins 5 and 6 are the drive select,
but be aware that these are switched as you chain the drives through. I
usually connect the drive right to the drive A (Atari's) out port.

On the IBM Style drives, pins 10 & 12 are the drive selects. Use
drive select 0, (pin #10, in the Ibm style)

This should help you in making the drive work correctly. One more
note here. You will have to obtain (or write your own) program that will
tell the ST that you have a 5 1/4 drive connected and to slow the seek
rate down. The 5 1/4's cannot and will not work at the default seek rate.

Good luck!

OK, where did this come from, how can we get the reworked ADVSYS, and, most important -- are there docs on how to program it? The original ADVSYS is fascinating but ultimately frustrating because the docs don't give you enough information to actually program the durn thing!

You're correct, Farrell. The 40 folder limit still exists in the ROMs. We still recomment FOLDRXXX.PRG as the fix for the problem.

Which ST periodical was this? I thought we had most of them trained to call and verify information before printing things like that.

*** FLAME ON ***

What good does it do to start rumors like this?

Do us all a favor, if you need something to talk about, discuss the weather.

I'm not saying that it wouldn't be nice to add features to the machine. But, we're not adding this one at the moment. And there are so many rumors getting people jazzed up for nothing...

The rumor mill in our community has gone a bit haywire lately. There's enough going on without people making things up.

Most ridiculous rumors of 1987 awards:

1. The blitters didn't work, so we're using kludged-up Amiga blitters.

2. The blitters partially work, so we removed 4 of 8 functions from them.

Please, folks, give us a break. We're easy enough to talk to if you want to ASK a question. Sometimes it seems that rumors are so much fun that their veracity has no bearing on how they spread. Sometimes they spread AFTER the facts are clarified -- fiction being more fun, I presume.

*** FLAME OFF ***

Sorry folks, but it's been a rough year.

Best to all for 1988! Hope you're having a good holiday season.

Subject: Re: Multiuser BBS
To: info-atari16@score.stanford.edu

In article <1479@saturn.ucsc.edu>, koreth@ssyx.ucsc.edu (Steven Grimm) writes:

> The ST's BIOS is re-entrant. GEMDOS is not. (I have a multiuser BBS
> system to prove it...)

OK, Steven, where's my copy of the multiuser version? And whatever hardware it takes to make it work. Atari Base is waiting...

Maybe I'd better backtrack a moment. Here in Atari, we run a free BBS for users. It's known as Atari Base, and can be reached at 408-745-5308.

Here's the rub -- we run 5 lines into 5 separate systems. The line you get through to is simply the first available line. But, if you leave a question on that line, you'd better make darn sure you get back to that line.

We're looking for a solution. We need a way for the lines to talk to each other. Solutions that have been discussed, in order of preference, are:

1. Multi-port RS232 box that lets several modems talk to one ST. The advantage is that we'd need one computer instead of 5. The disadvantage is that if the one system goes down, everything dies. We're willing to live with this, because system crashes have been extremely rare in the 2 years since Atari Base opened in its current configuration.

2. Network that lets each line share messages. At one time there was talk of trying a MIDI-based network, but work on this was shelved by QMI due to the inability to resolve conflicting RS232 and MIDI interrupts. Maybe "PromiseLAN" will solve this one.

3. Using a system like Fnet or Fidonet and having lines call each other to pass messages. Not too elegant in my book, and lines are only updated at intervals (probably daily), but we could do this today if we wanted to.

The other burning issue is, which software to use? We're currently using the Michtron BBS. Michtron has abandoned its plan to sell a hardware multiport gizmo because the engineers in the UK who were working on one couldn't get it to work.

FoReM 2.0 supports Fnet, so if we wanted to go to approach #3 we could do it. But with the number of novice callers we get, I'm a bit leery of using FoReM. Any comments to the contrary, netlanders?

NiteLite Systems now has a hardware device to let 4 or 8 modems share an ST. Their BBS program supports this. But... well, I used NiteLite on the 8-bit before we went to the ST on our board. I like NiteLite's message facility, but the program needs improving in the user log (not sorted at all) and the download area. Paul Swanson, NiteLite's author, is working at making improvements, and is very willing to take criticism and act upon it.

BB/ST is very powerful, and Steven Grimm is working on the multi-line facility. But we're still waiting on some hardware. QMI is a great little company, but I know they're (almost) as overworked as we are at Atari. So, timetables for this are in doubt. Also, BB/ST's tree-structured message base is not my cup of tea.

And then there's BBS Express ST. Keith Ledbetter is doing a nice job on this one. The message base and file areas work well. But there's been no hint from ICD about the prospects for a multi-line function. I'd like to hear of one, because I like the program, which has a nice extra for us -- the script language for it would make development of an online order entry system fairly simple. It would be a boon to users to allow them to order spare parts online.

One last thing -- we're committed to running the whole thing on Atari equipment. Partly because of budget (total cost for system hardware out-of-pocket to date has been $0), and mainly because it's a good excuse to push the envelope of what can be done on the system. The makers of BBS programs would love to see us use their program, because it's a great promotion for them. So, I tell them to give me what I need! Maybe some day it will work.

Just to not irritate anyone, I'm aware of the PD program STadel, but this one gave new users fits when I tried it at home. And there's CBBS from Oasis, which just came in and hasn't been tried yet. No word on multi-line functions here either.

Any helpful advice from netland?

> (discussion about errors being probable with too long a cable)

Just having obtained a SH205 with a 85cm cable (here in Holland it is prohibited by law to use inches) I followed Landon's suggestion in a simplified way: just 2000 times 'cmp aap noot >> mies' with aap, noot identical 64K files. Cmp did

not report any errors on this 256M data transfer in spite of various lamps,
a monitor etc. being switched in the neighbourhood. And I rather like the
longer cable.

My questions to IDRIS users:
- An emulated MMU seems a good idea if there is no hardware. But doesn't that
make the OS very slow?
- Any experience with porting UNIX software?

Does anybody know whether IDRIS is available in Germany?

In my first letter I mentioned the OS's RTOS-UH and EUMEL. Several people
asked for more information about these. I don't feel too competent...
If there is somebody who knows them well and is ready to write an article
about them (or one of them), I'd be grateful. If not, I am willing to look
up the magazine articles and to extract a short characterization.

Subject: Hard drives for the ST
To: info-atari16@score.stanford.edu

I have noticed a few requests on the net for information regarding
hard drives, hard drive kits, and the like for the ST. I have just
purchased a "TAMI-HD40" hard drive system from FutureDOS, and am *very*
happy with it so far.

I own an Atari Mega-2 ST and required a larger disk capacity in order
to run GEM, Magic Sac, and OS-9/68000 efficiently. The single drive system I
received from FutureDOS is in a long enclosure that is designed to accommodate

a second half height drive.
Since the system is custom made, I ordered the 44 Mb (formatted) hard disk configuration, for which I paid $1400 Cdn.. Other capacities are available upon request. Also, all of the hard drive systems are fully assembled and tested, so reliability is assured.

If you are looking for a high quality/high capacity hard drive system at a reasonable price, then this may be the thing for you. You can reach the folks at FutureDOS by writing them at

FutureDOS,
1207-120 Torresdale Ave.,
North York, Ontario,
CANADA, M2R 3N7.
Tel. (416) 736-0321

Christopher Parkinson
yunexus!gen1!yuplanet!chris

BTW-Standard disclaimer...I am in no way affiliated with FutureDOS, I am just another happy customer!!!

From: mnetor!utgpu!parora@uunet.uu.net (Pavneet Arora)
Subject: EasyDraw XX.XX
To: info-atari16@score.stanford.edu

I saw a demonstration of EasyDraw recently, the version # of which I don't know. I have a few peeves about the package which prevent me from purchasing it. Since I do need an object oriented drawing package I wanted to confirm that my objections are legitimate. If they are, and if EasyDraw is listening then please take them as suggestions.

1. Text cannot be rotated. (FATAL if you want to draw rough graphs). The closest you can get is something like:

R
o
t
a
t
e.

Not too useful if you are considering drawing architectural plans which require sideways printing for a better fit.

2. Exiting will always request if you want to save your file even if you have made no changes since the last save.

3. You have to explicitly select an object and then click again to move it. A single click should suffice the way it does with copying files etc.

4. The default for text should be justify off. I usually use
text as labels and can't see why justify should be on. I also
forgot most of the time to change justification when entering
text so that I had to go and change text attributes - a real
nuisance.

Some of the features I wish had been adopted from MacDraw:

5. A cubic spline fit (called SMOOTH and UNSMOOTH in MacDraw).
A really useful feature when one wants to draw gaussians and
sine waves etc. the way I needed to for my thesis.

6. The ability of picking a larger than one page size for the
drawing and then having EasyDraw print it out serially page
wise. This allows more complex drawings to be mosaiced easily.

Has anyone had similar experiences?

Subject: WordPerfect Update
To: info-atari16@score.stanford.edu

Just a note for WP users. The new update is supposed to be
out in early January. Since I didn't get any response to my
previous posting about the numerous bugs in WP I am not really sure
if any WP users actually exist. 8-{)

In response to Neil Harris' comment that the support is excellent, I have
a few comments of my own:

1. No company, software or otherwise, should be able to release
a product that doesn't even come close to working.
Bugs are one thing - fatal bugs another. I use the following
analogy - If I approached WP and asked them to give me
a copy of the software, and then told them that I would pay
them in a few months i.e. whenever I could afford it, I would
not expect them to hand over the package. And yet, WP has
taken money from users and then handed over a useless package
without ever notifying any of its users that there are problems.
And when a user tracks down the bugs and calls WP, they say
they are aware of it and a working version should be out soon.
Soon in my case has meant 3 months now, and I still don't have
a working version.

2. A company that only includes its UTAH address for technical
support, even in packages sold in Canada can hardly be seen
as being concerned for all of its users. By the way the (800) number
doesn't work from Canada so that you have to call WP on your
own expense during the day at full rate. Technical support

does exist in Canada from J.B. Marketing in Cornwall. Their
phone number is : 1-(800)-267-1731.

3. Part of servicing a product means keeping in touch with the
buyers and users and being above board about things(i.e.
through bulletins). I have not seen
any indication that WP considers this a priority. This is
critical in the present case where there must be bewildered
users trying to figure out why a $595 software package doesn't
work.

I think the larger issue here is the ethics with which high tech companies
operate. Personally, I don't feel that WP has thus far exhibited anything that
qualifies it for the praise that Neil Harris had to offer. My experience
has been in dealing with WP both in Canada and the US for the past three
months now.

From: wayrynd@jacobs.cs.orst.edu
Message-ID: <1803@orstcs.CS.ORST.EDU>
Source record: 255160

Jonathan Nagy wished to be informed what events are represented by I/O
Port bits 0-7 listed in the MFP 68901 chip interupts...

bit # function
0 Centronics busy
1 RS-232 data carrier detect
2 RS-232 clear to send
3 reserved(not used)
4 keyboard and Midi interrupt
5 FDC and HDC interrupt
6 RS-232 ring indicator
7 Monochrome monitor detect

If you need further help in implementing any of these interupts let me know
via e-mail, and I'll help as much as possible.
(I posted this to the net instead of a email due to the fact that it is
something that stumped me for quite awhile, and I hope to save others the
hassle of finding it!)

No, Hypercard for the Mac is virtually a complete programming (or maybe, better, working) environment which overlays the O/S. It *can* be used for ZoomRack-like record keeping, but if that's all you do with it, it's a bit like using an atomic bomb to kill flies. There must be a comp.sys.apple.mac meeting about (or something like that), and if so, I'd bet they could clue you in.

Just a not to point out that 'Atari' policy varies depending on which 'Atari' you are talking to. For example, in the UK, and when I asked, in addition to the non-disclosure agreement, they said they also required you to tell them what software you were planning to write. I backed off and went for third-party stuff at that point.

The point of this is that if you want to know what is available from Atari, when, for how much, or whatever, you're best off actually contacting Atari. (If they will talk to you, at least. Atari UK *are* pretty good at *that*, but that again might be subject to regional variation.

1064. Re: Multi-tasking? A nightmare...

Source record: 255164
Cross-posted to: comp.sys.atari.st,comp.sys.amiga

Oh, <deleted>.

NO ONE SAID MULTI-TASKING IS USELESS. NO ONE WAS FLAMING ANY MACHINE FOR HAVING IT.

I'm sorry I spoke. Yes, M/T is nice/handy/whatever, but I still haven't been convinced that it is the be-all and end-all, particularly for most 'home users' (non-developers? come on, you know who I mean, I hope.)

In the interests of net peace and harmony, I should be reachable by any of:

Smee at UK.AC.BRISTOL (JANET/UK)
Smee at UK.AC.BRISTOL via UKACRL.BITNET (BITNET)
Smee at BRISTOL.AC.UK thru any of the ARPA gates that support domain addressing
or
pes at bath63 via whatever return address you can work out from the header of this message.

Send further flames to me directly. (Some mailer enroute will probably bounce them anyway, so I shouldn't have to read much :-)

Meanwhile, someone needs to set up an electronic mail study group, because I tried when writing the original question to make it clear that I was honestly seeking information, rather than trying to start another flame war. Obviously I didn't get it right -- which appears often to be a problem with this form of discussion. Sorry. (And, P.S., these groups are probably not the place to discuss that. Where is?)

1065. WordPerfects???

Newsgroup: comp.sys.atari.st
Date: 1988-01-08 13:31:52 UTC
From: gaspar@ALMSA-1.ARPA
Message-ID: <8801081341.AA10025@ucbvax.Berkeley.EDU>
Source record: 255165

I've been considering WordPerfect, and I'm getting a little confused. It's as if there are two different WordPerfects. On the one hand, Pavneet Arora writes from Canada and says:

>In response to Neil Harris' comment that the support is excellent, I have
>a few comments of my own:
>
> 1. No company, software or otherwise, should be able to release
> a product that doesn't even come close to working.

On the other hand, Rich Dankert replied with glowing praise to a request for information on WordPerfect:

>In article <2143@cup.portal.com> RJknees@cup.portal.com writes:
>>Hey everyone! I'm looking for someone who has (or has used) WordPefect on
>>the Atari-ST. I'm thinking of buying this software!
>

...answers to questions 1-4

>>
>>5. Any other opinions or comments RE: Wordproccesing on the ATARI-ST
>>
> Contrary to all the comments from user's of Word Perfect in the
> negative aspect, I can say that the version I got didn't have all the
> bugs that I had seen mentioned. In fact Word Perfect Corp. is

> one of the best software makers that I know of. If you OWN the
> program, and have a problem with it, and they have a newer version
> of it, they will send it to you, second day air sometimes.
>
> This is one software maker that really backs their product!

What's the deal here? Are we talking about two different versions of WordPerfect for the ST here, is there a different version in Canada, or does Pavneet Arora use features that Rich Dankert doesn't? ? Can someone clarify? Also, some discussion of other peoples experiences would be great.

And, yes, Virginia, there is such a thing as multi-tasking ;-).

Cheers--

Al

Has anyone (Neil?) seen both WordPerfect and Microsoft Write? If so, it would be nice to hear how they compare. I saw WordPerfect ST advertised for around $250. Is it a whole lot better than Microsoft Write (will be :-)) at $129?

Cheers--

Al

Hi all, I have some questions to ask:
1. Can you hook an amiga up to a ST colour monitor?
2. If you can hook up the monitor, how much would a used 1000 cost in CDN dollars?
later
Barry

1069. Status of comp.binaries.atari.st?

Newsgroup: comp.sys.atari.st

From: tim@brspyr1.BRS.Com
Message-ID: <2364@brspyr1.BRS.Com>
Source record: 255169

A lot of the other moderated groups have been empty for a while too,
and a few of them have recently posted a status of what the have in
the queue and when we can expect to see it.

Could we get this kind of update for comp.binaries.atari.st?

Its been weeks since we've seen anything, and it would be nice to
know that it's not because nothing has been submitted.

{ this is not a flame at anyone, so please don't take it as one.
I would just like to know if I should expect anything soon }

Thanks

[Good morning, Mr. Line Eater...]

Neil,

With STadel, you may not be able to leave a public message directed to a person, but if it's public, why not simply put the recipient's name on the first line, and if need be, send them Email saying that there is a public message in such-and-such a room. Also, those people most likely to get public messages (such as yourself) could have a room (message base) for that sole purpose. With STadel, you can have 64 "rooms" on a system. You could have 5 different boards with a number of netted rooms as well as having a purpose to each separate board; say, one for graphics, one for MIDI, etc. If you wanted to net with Atari Canada, you could even net some rooms with them. Messages in the rooms can be netted automatically or you can give the general public netting privs.

I, personally, don't think STadel lacks in the up/download department either, but it is "different". Rooms can be made directory rooms. You can download a file right after you read comments about it if you want without having to leave the message base or going into a "file" section. You can send files from system to system through netting. You can make directory rooms that are either upload or download only. The only thing I find at all lacking is the description area. People tend not to describe their files well.

As for new users on STadel, there are some tricks, but once people are used to it, it is fast and easy, and best of all, NOT redundant! There are help files and tutorials available. Most of the STadel users I know (including myself) caught on very quickly. BBSers who are serious tend to be fairly clever about such things. A simple explanation that the BBS is like a large building where you wander from room to room reading new messages and leaving messages usually helps, as does explaining that everything you receive from the BBS is done with some kind of a Read, and everything you give to the BBS is done with some kind of an Enter.

In case some of you hadn't figured out, yes, I run one of these beasties. If you want some more information or would like a little tutorial about using STadel (which also comes in Amiga and MS-DOS flavored Citadels, btw), drop me a message. It may take a day or two to get back to you, but I will indeed get back to you. There are a bunch of addresses where I can be reached down below...

Neil, I have had trouble finding a path to you from Bitnet, I'm afraid, but I haven't given up hope yet! *grin*

1071. Atari ham radio net info

Newsgroup: comp.sys.atari.st
Date: 1988-01-08 19:34:21 UTC
From: jhs@MITRE-BEDFORD.ARPA
Message-ID: <8801081934.AA25296@mitre-bedford.ARPA>
Source record: 255172

This may be old news to many readers, but I just learned about the Atari Microcomputer Users' Net, a ham radio discussion group focused on using Atari computers, especially in ham radio applications (but not exclusively). The net meets Sundays at 1600 Zulu (GMT) on 14.325 MHz. (1600 Zulu is currently 11 AM Eastern time, noon during the summer.) David Byrd, KD7VA, is the Net Control Station. Dave is the creator of a well-known 256K plus upgrade for the 800. Gil, VE4AG, publisher of Ad Astra, is usually also on frequency. The group maintains an extensive disk library, emphasizing but not limited to, ham radio applications. Both ST and 8-bit software and hardware interests are covered by the group.

Readers who are not hams would need to find a local ham to participate actively in the net, but they might anyway enjoy listening in on a shortwave receiver tuned to 14.325 MHz on Sunday mornings.

IFF stands for "Interchange File Format". It is a stanard for creating
file standards. The intent is easy transfer between machines and
programs. Very nice.

There are IFF definitions for Musical Scores, sampled sound,
digitized pictures, etc.

You can purchase the entire "IFF manual" for $20 from:

1074. MULTI-TAXING

Newsgroup: comp.sys.atari.st
Date: 1988-01-08 21:27:00 UTC
From: F27FRAJP@CARLETON.BITNET
Message-ID: <8801090114.AA23175@ucbvax.Berkeley.EDU>
Source record: 255175

THE oddball discussions on multi-tasking have made me wonder why no one has thought of the obvious use-- figguring out your taxes. I don't know if the US system is as silly as Canada's, but what has always bugged me here is that you have to fill out innumerable different schedules and calculate them depending on where your money is coming from, because different sources of income are taxed or treated differentlty. So you run your tax program. All is well until it asks you to fill out sked 4, capital gains from real estate. So you stop and start filling in what property you bought, how much of it you sold, what proportion of the gain is taxable, etc. And you go back and fill in one figure. Then it asks you about dividend income from domestic corporations (taxed at one rate) and from foreign corporations (taxed at another) and you stop to figure that one out. Then it asks you to fill in your income from the oustide consultancy work you've done that year, (minus expenses allowable) and so on and so on. Does no one see here what multi-tasking can do? In the background you can have a batch of separate schedule programs doing the dog work all at once and feeding the results into the main tax program.
Software writers who haven't yet thought of this -- go ahead and use my idea. Just remember to send me a copy of the program. Canadian form, please.

>

In case you haven't already gotten an answer on this one, yes, there is a real program like this. If your machine is defective, and your dealer can't fix it or whatever, you can send it to Atari along with a flat fee and it will be replaced. (Note: _replaced_. So, if you have any strange upgrades that you installed yourself, you were warned.)

Anyway, the fees are as follows:

520ST $ 95
520STfm $115
1040ST $125

Box the dead unit up and send it (along with a letter explaining the unit is defective, and that you'd like it replaced) to:

Atari Corporation
390 Caribbean Dr.
Sunnyvale, CA 94089
Attn: Door 17

Hope that helps!

>to a way to avoid ever starting gem when booting would be nice.
> Jeff Anton

Well, I did reply to Jeff by mail, though I'm unsure of the path
that was used, however, I believe that this will be of interest to the
Atari ST community on the net. Therefore, here is the information
from the mail that I sent to Jeff. I'd suggest filing it and reading
it at your leasure.

[..... Cut Here .....]

Now for the information at hand --

GEMDOS executable file format:

The GEMDOS executable file consists of a header, text segment,
data segment, symbol segment and relocation segment.

Conventions used: USHORT = 16 bits unsigned
ULONG = 32 bits unsigned
LONG = 32 bits signed

GEMDOS header:

```
struct gemhdr {
USHORT gh_magic; /* always == 0x601A */
ULONG gh_tsize; /* size of text segment */
ULONG gh_dsize; /* size of data segment */
ULONG gh_bsize; /* size of bss segment */
ULONG gh_ssize; /* size of symbol segment */
ULONG gh_reserved[2]; /* 2 longs, "must" be 0 */
USHORT gh_reserve; /* Reserved, " " */
};
```

The text and data segments must have even length.
The magic number resolves into a "BRA .+1C" instruction.

The TEXT segment:

This section of the file starts immediatly following the
header in the file (offset 0x1C). All relocatable references
must be long and word-aligned. The GEMDOS program loader
adds the address of the beginning of the TEXT segment to

all relocation references. [see relocation format, below]
After the program is loaded, execution begins at the first
word in this segment.

The DATA segment:

This section of the file starts immediatly following the
TEXT segment. (offset 0x1C+text_seg_size). Relcatables
are TEXT segment based, and relocated in the same manner
and with the same restrictions as the TEXT segment ones.

The BSS segment:

This is not stored in the file. It is allocated at runtime
by GEMDOS (actually, by the runtime startup.)

The SYMBOL segment:

This contains symbol table information for DRI linker style
executables. For Mark Williams C style executables pre 3.0,
this segment is empty. As of 3.0, this segment holds debug
and symbol table information in Mark Williams format. Write
or call Mark Williams for more information on this.

The DRI symbol table format is:

```
struct drisym {
char ds_name[8]; /* null padded ident. */
USHORT ds_type; /* symbol type flags. */
LONG ds_value; /* signed 32 bit value. */
};
```

Type flags for the ds_type field:

```
DEFINED 0x8000 defined symbol
EQUATED 0x4000 equated symbol
GLOBAL 0x2000 global symbol
EQUATED_REG 0x1000 equated register
EXTERNAL_REF 0x0800 external reference
DATA_RELOCATE 0x0400 data based relocatable
TEXT_RELOCATE 0x0200 text based relocatable
BSS_RELOCATE 0x0100 bss based relcatable
```

RELOCATION (fixup) segment:

The relocation segment begins with a longword that specifies
the offset into the text segment of the first relocatable
reference. This is followed by a stream of unsigned bytes
that specify the next fixup. A zero byte flags the end of the
relocation table, a value of 1 means add 254 to location counter
and fetch the next byte, any other even value is added to the
location counter and the longword at that address is relocated.
All other odd valued bytes are reserved for future use.
If the initial longword is 0, there is no relocation information.

Loading and relocating:

When GEMDOS loads a program file through Pexec() it goes through
the following steps: The largest segment of free memory is
allocated to the process and a prototype basepage is built at
the beginning of it. The program file header is read and the
basepage is filled in. The text and data segments are then
read into memory. The symbol segment is skipped and the first
longword of relocation information is read into the fixup location
pointer. If this value is 0, the system proceeds with the action
specified by the Pexec() mode. Otherwise, the address of the
text segment is added to the fixup location pointer and the longword
at that address has the address of the text segment base added to it.
The loader then reads the relocation stream until it gets a 0 byte,
if a byte is 1, 254 is added to the fixup location pointer and
the next byte is read from the relocation stream; any other even
non-zero byte is added to the fixup location pointer and the
longword at that location has the base address of the text segment
added to it. Once a zero byte is encountered in the relocation
stream, Pexec() proceeds to either set up for execution (loading
appropriate registers with appropriate values and then jumping
to the first location in the text segment) or returns the basepage
address to the caller.

Notes on fixup generation:

o All relocatable values must be word aligned longwords.
o Relcation references to text segement locations are zero-based.
Data is loaded directly after the text segment, and relocation
references to data segment locations are based off of the text
segment base, thus a relocatable reference to the first data location
would be the text segment size. BSS is "loaded" immediately
following the data segment, thus BSS references are the offset
into the bss segment added to the combined size of the data and
text segments. This makes one-pass linking difficult.

Other comments:

o All ROM versions of GEMDOS released so far have a bug which
prevents loading of programs with relocation segments > 32K bytes.
Atari has confirmed this bug and says it will be fixed in the
next version of GEMDOS. The date this was written is 8-January-1988.

o You will need references to GEMDOS to understand the basepage
and other GEMDOS issues. I recommend the Mark Williams C manual
for much of this information.

o It is up to the runtime startup code, which must begin in the
first byte of the text segment to set up the program stack and
free unneeded memory back to the system. Look at just about
any vendors runtime startup module source for how this works.

o Some documents have the header wrong, listing 3 reserved longwords
at the end. There are only 2, plus a short.

Disclaimer and plea:

I work for Mark Williams Company. I am responsible for much of the Mark Williams C compiler package for the Atari ST, and have made considerable contributions to the documentation for that package. Despite this, the material contained in this message is not a Mark Williams Company product. All opinions in this message are my own and have not been cleared by my employer. Source record: 255182

I would like to know if somebody can explain this one.

I was copying C to the hard disk (3 single sided disks). The first disk gave me the "data on drive A may be corrupted" message. Trial and error turned up 3 files on it that wouldn't copy. The rest of the files and the other two disks copied okay.

Two of the "corrupted" files were text, so I double clicked on them to see what was salvageable...and got the whole file. The third, a program, wouldn't load. So I fired up Disk Doctor and checked the directory and FAT (including the duplicate). All okay, and no bad sectors in the files.

At this point I turned everything off and rebooted without the hard disk or any desk accessories and tried to copy the files to another floppy. Still got the "data on drive A may be corrupted." I tried the disk in B: drive...same error. Tried various copying utilities...no go. So I cranked up my floppy version of C and wrote some copyer programs.

The open function didn't like the files, so I went to Rwabs and used the FAT to trace the file. Reading the file by cluster bombed with status -1 (general error...thank you DRI). I put in a gets(str) before the Rwabs so I could step through...still bombed. Finally, I had it read sector by sector with a gets() before each Rwabs, and it worked!

So now I've got all the files copied, but I'd like to know why they had to be read a sector at a time with pauses. It makes me wonder how many other corrupted files I might have been able to save if I'd worked at it a bit more...

From: UD138985@NDSUVM1.BITNET
Message-ID: <504UD138985@NDSUVM1>
Source record: 255183

Hello there...

I recently got the latest version of Krabat and got it all decoded, etc.
I am having troubles with the picture files. Everytime I start the game
by double clicking on the file it starts up, asks where are the pictures in
an alert box, and aborts. I put the pictures in the root directory, in a
subdirectory called pictures like I did with the origional, and in other
directories with every 'logical' name I could think of. Has anyone else had th
is problem? What am I doing wrong??? What directory do the pictures go in?

Thanks in advance for any replies.

1084. starting up UniTerm

Newsgroup: comp.sys.atari.st
Date: 1988-01-09 04:42:34 UTC
From: aoki@postgres
Message-ID: <98@pasteur.Berkeley.Edu>
Source record: 255184

Has anyone succeeded in autostarting UniTerm?
I've tried:

sticking UniTerm in an auto folder
EFFECT: three bombs.
sticking UniTerm in an auto folder with its aux. files
EFFECT: screwed-up screen with a locked kb.
kicking off a shell from the auto folder, then calling
UniTerm from the shell init file
(I've tried ash 0.70 and the latest version of Gulam)
EFFECT: ash - random screen
Gulam - UniTerm screen appears, then disappears
and dumps me back into Gulam

I'm using UniTerm V2.0a 005, the version archived at cs.orst.edu.

Any suggestions? It seems so pointless to have to doubleclick the
@#$% icon every time.

>uunet.uu.net!gaspar@almsa-1.arpa

I will reinterate again. I have had no problems with the version of
Word Perfect that I have. I use the program on an explanded 520 (1 meg) and
use a ramdisk in conjunction with it. I have yet to have *any data mixed up
or otherwise corrupted to date.

I use WP with my MonoChrome monitor and have yet to see it screw up
the display or any other such things that I have read in my travels about the
different services here in the usa. I have have nothing but good to say
about this product.

I have used it to pop out important documents to many places where
the way the document looks is 1/2 the battle. Of *all the W/Ps that I have
used this is the one that gave me an output to my printer that was perfect.

As far as getting updates from the CO. I cannot say that I have had
the need to do so. My program works great for me, so no need. The reason
for mentioning the CO.s backing is that others have had to get a bit of
help or have encountered a bug, and WP corp. has shipped them a different
program of the same version, and there bug was gone.

I can only say that *yes there are others that may use the program
and have problems with it, but I am not one of them. Of all the reports

that I have read, I am still looking for the same to happen to me, but
am plesently pleased to say that they have not, at least to this point.

I think the program is great, and worth the $$$ for everything that
you get.

UUCP: {Ihnp4,uwvax}!uwmcsd1!lakesys!rich
Discalimer: The words,ideas,and expressions are my own, and not nessasarily
always correct, and I have been know to be wrong.
I am not in any way or form tied into Word Perfect Corp. Just a very
satisfied customer.

.DVI files are 'Device Independent' files as produced by the TeX formatter. You then need to find a machine sommewhere which has TeX, and which has a DVI to specific device 'conversion' program (aka 'driver'). (DVIST which was posted some time ago won't hack it, because UG.DVI references font files which were not present with DVIST. I have heard rumours of a DVI2PS program which will convert UG.DVI to a (huge) PostScript file, which ought to be more amenable to being (painfully) battered into a legible form, in the absence of a printer. I haven't seen DVI2PS myself, though.

Simon, if you're listening, how about putting out a 'human reabdibledable' form of UG.DVI?

1088. Re: Multiuser BBS & HDSCAN/DISKTOP Info

>We're talking semantics here. I know you can leave private "email" in
>STadel, but you can't leave a public "message" addressed to someone.
>

Neil,
If you look at this message, you will see that I have effectively addressed my message to you (without even having to type in your full name...) If you want to reply to someone in particular on an STadel in a public group, isn't it just as easy to put their name into the body of the message like this as it is to be prompted for the name in a program? It's true that if you (R)eply to someone on other BBS's, you don't have to type in their name, but is that such a big deal? In fact, you can speak directly to more than one person in a public forum in this way...sheeze...in fact...

Dan (Mr. MWC),
Thanks for the info on big arrays...now that hdscan is released on Unix I should be able to get a new version released on the ST soon (with no messy limitations).

Lee (and other DISKTOP users),
A new version of disktop is coming up soon (I finally found out why the new OSS Pascal was flaking out on me). I am looking at eventually trashing the code, however, and hatcheting up a special version of HDSCAN to become a future version of DISKTOP...that way I can keep track of full hierarchy and also have a tool that will work on all the floppies on my Unix box...with all of hdscan's features of course. I am really surprised that there aren't any tools like this already on Unix systems...or if there are, they are so expensive that I never hear about them.

You CANNOT start a program that accesses any part of GEM from bootup
AUTO folder. GEM is initialize after the AUTO folder programs are run.

However there is a solution, but I have not tried it with UniTerm. There
is a program (I think it was posted to the net) that is called something
like GEMSTART. I don't exactly know how it works, or what limitation are
put on it (if someone out there know, please post it) but it should do
the trick.

>Thanks,
>Jonathan Nagy

I didn't think it was possible to have an event waiting (ie. the window coming down) and have output to the screen at the same time. If your talking about the menu overwriting the window text, that is also impossible because the AES saves all the screen under the menu that is coming down. As for dialog boxes, your best bet to to open a window underneath it, and when the dialog box is gone do a window redraw from the message event that will be waiting.

>Yesterday I FTPed and downloaded UniTerm v2.0a (thanks, whats-yer-name at
>Oregon State) to find, to my chagrin, that the documentation is in DVI format.

You're welcome. As the one who made UniTerm available for FTP, I have
had a few other such queries about the DVI documentation file. So:

>Well.. what's DVI? How do I get this file full of gibberish to make some
>sense? Be warned that I have no printer..

DVI is the output of the TeX (or LaTeX, in this case) text formatter.
It is a device-independent format for bitmapped display devices (such
as Sun displays, Apple Laserwriters (PostScript), Imagen laser printers
(imPress), etc. Typically, one runs the DVI file through a program
which converts it to some device-specific format.

Simon Poole's Users Guide (about 65 pages) for UniTerm 2.0a prints out
beautifully on our Imagen laser printer, but not everyone can print
DVI files. Luckily, we have here a program which converts DVI to
ordinary text. The result is not very pretty, and requires more than
80 columns to print out, but it is easier to read than gibberish.

Get the README file (anonymous FTP on cs.orst.edu) to see which files
contain what (there is no need to retrieve them all).

>

Wrong Neil. Citadel has ALLWAYS (since I worked on Citadel over 5
years ago anyway) supported sending personal messages. I've always
suspected that you dropped STadel because you didn't really understand
large portions of how the system works and this just reinforces that
impression.

The system isn't all that hard to understand, it just breaks some of
the basic assumptions that many people make about how a bbs system is
"suppost" to work. If you really want to give it a fair trial, you
have to start by dropping a lot of assumptions... unfortunately, it's
easier for many people to reject something they don't understand
rather than taking the time to question their personal biases and
just-maybe discover a better way of doing things....

>you are on, rather than at a lowest common denominator level -- which I don't
>think would be doing anyone any favours.

We've worked out some fairly nice (at least, WE think they're nice) solutions
to that problem. Naturally, you're going to want to write a program in the
machine's native OS (or not use an OS at all) if you need to squeeze every
last bit of power from either machine; there are some things which can't be
generalized. But our OS (which is still unnamed at this point) will, for
instance, allow you to write an arcade-style game with good sound and fast
graphics that will work on either system.

>Right off, without thinking much
>about it, I wonder whether we could actually learn to talk together reasonably
>enough for it to take off. :-)

I don't know how to do that in assembly language. It must be a hardware
problem. :-)

>no one has thought of the obvious use-- figguring out your taxes. I
>...
> In the background you can have a batch of separate schedule programs
>doing the dog work all at once and feeding the results into the
>main tax program.

Umm, this would be a real waste of valuable programming effort for several reasons. First, even the most complex set of tax schedules that the government could ever imagine (and they appear to try every year) can be fully recalculated in real time even on my little 8 bit computers. Our computers can easily do 100 simple mathematical calculations per second, and the amount of storage necessary to keep all the possible forms and data structures resident in memory is well within reason.

Some of the best tax programs I have ever used were, in fact, on my old Atari 800. It had all the tax forms resident and you could move back and forth between 20 or so forms, always seeing how much you owed at the bottom of the screen. There are several good ones out for the ST now (and I assume the Amiga), although I am using an IBM PC one on the ST (under PC Ditto), which I have used for the last few years.

Another reason against multi-tasking in this area is programming simplicity. By removing the linearity of the code execution, you would be increasing the potential for programming errors, making debugging a nightmare, reducing the portability of the code, and generally just ignoring a fundamental programming tenant: KISS.

1100. WordPerfect - Differing opinions

Newsgroup: comp.sys.atari.st
Date: 1988-01-11 02:36:37 UTC
From: parora@gpu.utcs.toronto.edu
Message-ID: <1988Jan10.213637.7864@gpu.utcs.toronto.edu>
Source record: 255200

I am sorry for not responding earlier. Our site just received the INFO-ATARI 16 digest. I didn't realize there was any activity on WordPerfect.

ASIDE: Al Gaspar or Rich Dankert, if you could please send me a summary I'd really appreciate it.

I didn't get Al's original posting either but I did see Rich's response.

I too am at a loss as to our differing opinions. I will try to present some details that may clear up the situation.

As far as I know, there are two existing versions of the program with another one out in the US but not yet up in Canada. These are 10/10/87 and 10/28/87, both of which I have. You can verfify the dates by invoking the online HELP. It is on the top right of the HELP screen.

My configuration is as follows:

A 1040ST with a single DD floppy
Monochrome monitor
Roland 1012 9-pin printer (just another FX-80 emulator)
I believe this printer sells in the US as the Panasonic 1080i.

My problems stem mainly from using printer.prg. That is where there I have found most of the bugs. Of course, if there are bugs there then it is awfully difficult to get formatted documents for your printer 8{). However, there are bugs in WP.prg as well.

The critical problem for me was the following:

I was trying to get right-justified documents with a proportionally spaced NLQ font, i.e., use my printer to its fullest. I spent many hours skirting the plain sloppy bugs in printer.prg and finally got my character width defintion set up.

I then transferred this definition on the WP disk etc. so that I could use it. Now when I try to print the document, it prints it beautifully, NLQ, proportionally spaced font. At least it does the first time. Now without doing ANYTHING to the document and just asking it to print the document again, all of a sudden right-justification is forgotten and you get a non-formatted document. Nothing except getting out of the program and invoking it again will print documents right-justifified.

I can try to list other bugs as well if people are interested. I didn't know if netters would want to read about the intricacies of WP.

The only other thing I can really say is that I have written WP two letters with different lists of bugs. They have acknowledged that the bugs existed and the latest release (i.e. early January, the one I presume Neil was Beta testing) was actually scheduled for Dec 15, 1987. I was told by WP Canada (ala J.B. Marketing) that they had relayed my lists to UTAH and the Dec 15 release was delayed a month as a result of the list of bugs that I sent them.

I hope this helps us get to the bottom of this.

Hi, youse out there in netland.

I have an ST (520 + an extra 1/2 meg). I am looking for a C compiler to start exploiting the power of the box, but I can only find a few review of the compilers I can find ads for. What I want to know is -
How good is the documentation ?
How good is the Debugger ?
What other products (C++, microemacs, etc) will run with it ?
What other hardware does it support (68020, 68881, Stereotech Glasses, etc) ?
How fast is it ?
What is the editor / environment ?
How good is the Gem interface ?
How robust is it ?
How close to the K&R standard is it ?
Has it got unix compatible library calls ? (System 5.2 - I work on a Tower 600)
What is the price and where do I get my paws on it ?

The compilers I have heard about via advertising, but little else, are
Mark Williams C, Megamax C, Manx Aztec C, Alcyon, Lattice C, Hippo C (??).

Please send your replies to me or the net (their are probably a number of users who would like this info). I will try to summarize the answers I get (this is my first posting !) and resend out.

My address probably is ...!uunet!munnari!vuwcomp!dsiramd!pnamd!cstowe!greg which is out in the antipodes (NZ).

Thanks in advance,

Greg

Disclaimer - my bosses can't even work the net, let alone figure out what I put on it !

Take these stunned men to the Meditechs !

Sorry if you recieve this more than once - problems with sending as this is our first posting ever

1104. Absoft Fortran?

Newsgroup: comp.sys.atari.st
Date: 1988-01-11 12:33:00 UTC
From: FXDDR@ALASKA.BITNET
Message-ID: <8801111745.AA16273@ucbvax.Berkeley.EDU>
Source record: 255104

I am interested in finding a Fortran compiler for the ST. I've used Absoft Fortran on another machine, and it seems to have good reviews on the ST, but now I can't find anybody who sells it. I checked through several magazines and only found one that listed a "Fortran 77" (no brand given).
So what happened to Absoft ST Fortran? Is it still available somewhere? Are there some reasonable alternatives? Complex numbers and functions are important...GEM VDI support is also important.
Thanks,
Don Rice

1105. Atari HD info required - (nf)

Newsgroup: comp.sys.atari.st
Date: 1988-01-11 13:25:00 UTC
From: schwarz@infbs
Message-ID: <21600007@infbs.UUCP>
Source record: 255105

Hi Sirs,

I would like to abuse the Atari harddisk SH204 as a disk in a transputer system. Therefore a simple transputer link to ASCI bus interface is to be build. But due to lack of documentation I do not know the required handshake timing diagrams of the Datarequest (DRQ) and Acknowledge (ACK) signals.

My questions: Does someone outside know the timing specification for the asynchronous protocol of the harddisk ? I have seen a cycle time of about 750 ns for one byte transfer controlled by DRQ ACK signals driven by Atari St. Is it feasible to work with a cycle time of approximately 1300 ns ? Does someone know where to get authorized documentation for the harddisk ?

Any information about the disk is appreciated.

1106. HOTSHOT v1.6 Bug

Newsgroup: comp.sys.atari.st
Date: 1988-01-11 13:58:00 UTC
From: DMiddleton%pco@BCO-MULTICS.ARPA
Message-ID: <880111135820.663058@HIS-PHOENIX-MULTICS.ARPA>
Source record: 255106

The day after posting HOTSHOT v1.6 I discovered a minor bug in the checkers game. If you are winning so decisively that the computer resigns, then the game goes into an unknown state. To start a new game one must quit and restart the game.

An update v1.7 will be posted in the near future to correct this flaw. I hope to have it out soon.

1107. Atari Laser Printer

Newsgroup: comp.sys.atari.st
Date: 1988-01-11 14:15:03 UTC
From: rtb@ihlpf.ATT.COM
Message-ID: <3322@ihlpf.ATT.COM>
Source record: 255107

I was in my local computer store on Saturday and I saw
an Atari laser printer hooked up to a Mega ST. The salesman
showed me some Publishing Partner flyers that he printed out and they
looked really good. No "jaggies" on the larger letters like you
sometimes get on HP laserjet printers. The printer comes with several
disks that have a lot of fonts. All fonts for this printer are software
loadable (which means they should be cheap compared to font cartridges).
At the last minute Atari switched to the Cannon engine, eliminating a lot
of the problems associated with the liquid toner of the ricoh engine.
There is an additional box that goes between the printer and the computer
which might be used to chain the DMA port, this box was small enough
to sit nicely on top of the SM204 hard disk. The retail price of the
printer is $1995 but I think I could get it for $1600 from this
particular dealer. One of the emulations this printer can do is
Diablo 630 making it compatible with any word processor that can
talk to a Diablo 630. As most of us know by now the laser printer
uses the computers memory instead of its own. An advantage of the
printer using the computers memory is speed. I did not test the printer
in depth enough to determine how fast or slow it was.

We talked about about the wisdom of buying a printer that can only
be use on one computer. Like anything else there are advantages and
disadvantages. Normally, the biggest advantage would be support.
Unfortunately, looking at Atari's past track record my biggest
fear would be that some bug would be discovered that would make the
printer a nuisance to use and we would be waiting two years or more
for a fix. This fear is compounded by the fact that my SM204 seems
to be a victim of ATDI's (or whatever that hard disk utility is) inability
to properly mark bad sectors. I bought the SM204 because I thought it
would be the most compatible and have the least problems and I am finding
out the opposite is true.

I decided to take a wait and see attitude before I buy this printer. If
I feel I will get the support I need I will probably buy one.

[let's do lunch]

Wait wait wait!! Instead of jumping all over someone (Neil in this case)
for not having a complete understanding of a system with which you've
worked for a couple years, why not make an effort to simply explain?
I suppose maybe it's because I remember my STadel roots because it wasn't
all that long ago that I first logged into Pell and uttered a few *eek!*s
myself. Yes, folks! I was one of those new users who G'd (Goto) every
room in the system. (Mind you, this was in Pell's early days... which,
if I understand correctly, was the last time Neil really looked at STadel.)

STadel has changed a lot in this last year. Even though the basic concept
remains the same, it has become much more friendly to the new user who
takes the time to read the opening prompt of "[?]=menu, [H]=Help, [L]=Login".
I think most any new user can figure out what to do with those. Seeing
as the resulting blurbs are user-defined, almost anything can go in them.

How about if we back off flamingat Neill? Something tells me that flames
aren't going to endear STadel to the man's heart. (Or anyone's for that
matter! Who wants to try out a program where they may well get flamed
for not understanding something?!) Instead, why not try to explain STadel
from concept to practical usage. If nothing else, I think it reflects better
on the Citadel community as a whole.

Now... for those of you who are interested... (Neil?) I am working on
(slowly but surely) a tutorial/blurb about Citadel/STadel. Don't expect
it to be done in the next few days, but maybe in a week or two. When
I'm finished, I will mail it out to those who are interested (Neil? *grin*)
or post it to the net if the size is not prohibitive and there is enough
interest.

Holly (...!rutgers!indycms.bitnet!ihls400 or just IHLS400@INDYCMS.BITNET)

Have a day!

>
>Any suggestions? It seems so pointless to have to doubleclick the
>@#$% icon every time.

Paul, all your descriptions boil down to one problem... You're still trying to run a program that uses the AES system before AES is initialized. The solution is to use a program called BOOTMAKR.PRG.

This program allows you to create another program which, when placed in your auto folder, will run a GEM program (one that uses AES or VDI routines) just after the desktop appears without you having to touch anything... Since the desktop itself uses AES routines, the AES system is initialized when the desktop boots, and your program (in this case UNITERM) will run just fine...

I'd rather not send BootMakr via mail because my local usenet node is currently having problems with anything but 300baud and it would take quite a while for me to upload even a relatively small program. Check your local ST bbs systems... If you still can't find what you need, drop me a note and we'll see what we can work out to get the program to you...

I second the motion to have UniTerm v2.0a posted. I have an old version of UniTerm that doesn't even do xmodem. I'd welcome the chance to get the latest version with all the improvements that have been made since then. Unfortunately I only have access to usenet and have never been able to FTP anything from anywhere. Please post UniTerm to comp.binaries.atari.st. Of course I'll have to cope with the stress of actually seeing something posted to comp.binaries.atari.st but I'll make the sacrifice. Thanks.

A compiler can, under normal circumstances always use the jump table address
to reference the function. A smart compiler/linker could optimize some
of these into direct addresses, if the calling function is in the same segment
as the called function (and thus the segament is guaranteed to be loaded
already).

Anyway, the reason I am repling is that I have already done what you are
intending to do. Some minor changes needed to be made to gcc and
gas - these included stuff to tell gcc that ints were 16 bits (there are
problems with passing arguments for bios calls otherwise, also much faster)
and some changes to get gas to dump .o files that are usable on the sun
(so I could adb them there...). Other stuff that was needed was a program to
convert unix a.out executables to gem format, long multiplication/
division/modulo routines for gcc, and of course libc (which is still under
construction). If you want some/all of the stuff I have done just send a
note (I hacked 4.3bsd (vax) ld/strip/size/nm/ranlib so I can't just send
them to you - maybe diffs if you have a source licience?) The only thing
that is really missing is floating point routines - any sugestions as to
PD versions (in C or assembler) for these would be helpful.

> there is a public message in such-and-such a room.

Even more of a kludge. Do people really do this? I didn't think so.

> In case some of you hadn't figured out, yes, I run one of these beasties.

<grin> Stadel seems do inspire the same kind of fanatical loyalty among its sysops as does Zoomracks -- and I don't particularly love either one.

> If you want some more information or would like a little tutorial about
> using STadel (which also comes in Amiga and MS-DOS flavored Citadels, btw),

I am very familiar with STadel. I tried it out on my own board, and have used many other active STadel boards. Yes, there seems to be message traffic. But you're trying to sell someone (i.e. me) who is not a prospect.

> Neil, I have had trouble finding a path to you from Bitnet, I'm afraid,
> but I haven't given up hope yet! *grin*

I have. Email does not seem to make the transition from Usenet to any of the other nets. The mailer daemons keep reminding me of that.

>

For Christ's sake! Everybody with a debugger thinks he can out-think
the guy who wrote (and documented) a utility.

(It happens that you have the table wrong: $4E75 is an "rts" instruction.
The table starts with the next word, with date-address pairs.)

Atari is not so foolish as to think that a patch which works for current
and old ROMs (i.e. 6/1/1986 and older) works for all future ROMs. If
we say it works for ALL ROMS, PAST PRESENT AND FUTURE don't you think
we've put a little more thought into it than that?

Yes, FOLDRXXX.PRG works for ALL ROMS. It will work for ALL FUTURE ROMS.
(At least, all ROMs which have this problem.) I shouldn't have to defend
it like this, but I will spell it out:

For old ROMs, the location of the patch point is determined from the table.
For newer ROMs, a pointer to the patch point was placed at the end of the
OS header, so the address comes from the ROM itself.

That's how you make things work for past, present, and future.

The reason I am mad about this posting is that the LAST thing we need
is people to start rumors discrediting Atari's patches. When we do
try to fix something, please make sure of your facts before telling the
world that it doesn't work.

1122. Re: object code file formats

Newsgroup: comp.sys.atari.st
Date: 1988-01-11 23:15:17 UTC
From: apratt@atari.UUCP
Message-ID: <939@atari.UUCP>
Source record: 255122

First, thanks to Daniel Glasser for his posting. There are one or two things I want to clarify, though...

in article <2082@chinet.UUCP>, dag@chinet.UUCP (Daniel A. Glasser) says:
> ... All relocatable references must be long and word-aligned.

Clarification: all relocatable references must be longwords and must be word-aligned. (Another reading of the above sentence is, "They must be longword-aligned and word-aligned.")

> The BSS segment:
>
> This is not stored in the file. It is allocated at runtime
> by GEMDOS (actually, by the runtime startup.)

The BSS segment is allocated by GEMDOS. If you ask for 32K of BSS, your program will get 32K of BSS (as you can see by checking your basepage). What gets set up by the runtime startup is the HEAP, which is the space between the end of your declared BSS and your initial stack pointer. It is the size of the HEAP that you set when you assemble GEMSTART (for instance).

> The SYMBOL segment:
>
> Type flags for the ds_type field:
>
> DEFINED 0x8000 defined symbol
> EQUATED 0x4000 equated symbol
> GLOBAL 0x2000 global symbol
> EQUATED_REG 0x1000 equated register
> EXTERNAL_REF 0x0800 external reference
> DATA_RELOCATE 0x0400 data based relocatable
> TEXT_RELOCATE 0x0200 text based relocatable
> BSS_RELOCATE 0x0100 bss based relcatable

There are some more types than this: 0x0080 means "FILE" and is used by the linker (well, by ALN, at least, and possibly LO68) to show where a file starts. (The symbol name is the file name, and the symbol value is the address of the start of the text segment of that file (even if it doesn't have anything in the text segment)).

ALN also uses the next bit, 0x0040, to mean "ARCHIVE" -- this is an ALN-specific extension, and is only used in conjunction with FILE. The start of an archive is marked with a symbol of type ARCHIVE FILE, where the symbol name is the archive name. The end of the archive is marked with a symbol of type ARCHIVE FILE with NO name (all nulls).

Thanks again to Dan Glasser for this posting.

INFORMATION

----------------------------------------------------------------------

Date: 31 Dec 87 00:49:23 GMT
From: clyde!watmath!dalcs!silvert@rutgers.edu (Bill Silvert)
Subject: PrintMaster Icons
To: info-atari16@score.stanford.edu

It is a long time since a nice set of PrintMaster icons was posted to
this group. They are handy not only for PM use, but with a program by
```

Sol Guber (shareware) you can convert them to Degas format for use with Publishing Partner, etc.

I am looking for a tool to manage PM libraries. I would like to be able to read through a library and copy selected icons to a custom library. You can do this with PM itself, but the process is cumbersome. Does anyone have such a beast, or some related code that will help? What is the format of the library entries anyway?

Are there any more PD libraries lurking out there? A large set was recently posted to a BBS that I run (almost 300 K!), but I spotted a couple of proprietary libraries in it and had to pull it off. It is a real pain trying to figure out what is and isn't PD!

If there is interest, and if I can figure out what is PD in the arc file, I will post some of the libraries. Any information or any files and PM utilities that anyone can post or send would be welcome.

By the way, the file includes a program that is supposed to dump an icon library to the printer. It doesn't seem to work well, but the output on my SMM804 makes me think it may work on a true Epson. If you want to try it, send mail to ...!dalcs!biomel (if you send it to this address I won't send it -- You have to use the correct address!).

AGREED! I have been reading this board on and off for some time now. This due to many users on my system whom use st's. Multi-tasking requires very little "cleverness" and the OS often does the work for you. It doesn't take long to see the advantages and use them. For me, if I had to return to a single tasking enviorment it would be like some of you having to return to a 40 column screen (bleech). Your 68000 is mot likely barely used. Why not give it abit extra in the way of jobs? Multi-tasking makes you far more productive. Useless award - this is right. I would guess that the most likely feature to be seen on all future machines will be OS's that multitask. Why the heck should you have to stop working just because your OS can't "talk and chew gum" at the same time?

Subject: INTERRUPT PROCESSING
To: info-atari16@score.stanford.edu

How do you disable and enable interrupts from
1. The keyboard?
2. The SIO port?

In the documentation at my disposal (Mark Williams C and Abacus)
I can find the following table under Jdisint:

Interrupt # event
0 I/O port bit 0
1 I/O prot bit 1
2 I/O port bit 2
3 I/O port bit 3
4 Timer D
5 Timer C
6 I/O port bit 4
7 I/O port bit 5
8 Timer B
9 sender error
10 sender buffer empty

11 receive error
12 receive buffer full
13 Timer A
14 I/O port bit 6
15 I/O port bit 7

Half of these are self explanatory, but the other half requires
a mapping to atari st hardware events. Would someone be kind
enough to inform me what events are represented by I/O port bits 0-7 in
the atari 1040 ST? I presume that one of these represents a
keyboard interrupt and another an SIO interrupt; otherwise
I really need help!

Thanks,

Jonathan Nagy

> board for the ST cartridge slot. Any info on physically
> plugging into the cartridge slot would be appreciated.

I recently built a battery-backed real-time clock and a four
channel A/D converter to plug into my cartridge port. I bought
the board from,

Douglas Electronics
718 Marina Blvd.
San Leadro, CA 94577
(415) 483-8770

The board fits perfectly into the cartridge slot. It has holes
spaced at 0.10 inches, 20 rows by 30 columns, with 8 rows dedi-
cated for power and ground buses. The part number is 33-DE-40,
costs $10.00, they'll ship it however you want, and they accept
MC and VISA. I have nothing to do with this outfit other than
being a satisfied customer.

Subject: 520ST Jittery Monitor Woes
To: info-atari16@score.stanford.edu

I consider this problem to be minor, but I thought I'd see if anyone
has had a similar experience. After my computer (520 ST) has been
on for 1 to 1.5 hours, the *low resolution* display begins to get
jittery. It starts out very mild (one or two scan lines misplaced
a little) and then regresses to the point that I can hardly stand
to look at it. If I switch to medium resolution, the problem
disappears. Or, if I turn the computer off for a minute (just the
computer, not the monitor or drive) then turn it back on, the
display will be normal again for a while. Then the whole sequence
repeats. It's been this way for a long, long time, but I didn't care
too much because I almost always use medium resolution (the problem
never occurs in this mode). I just recently acquired some neat
(low resolution mode) games so now it's starting to annoy me. Although
the computer is properly ventilated, my guess is that something is
overheating. Any other ideas??????

Subject: Zoomracks (i.e. Hypercard's predecessor?)
To: info-atari16@score.stanford.edu

I was just reading this quarter's STart magazine (Wint87), and came across an article on Zoomracks - an ST product which sounds a lot like Hypercard for the Mac. One major difference being that Zoomracks has been around for 3 years.

The article is interesting. If anyone has used the product, perhaps they can post their views.

Why hasn't this product come to light earlier? One thing I did notice was that the screens used in this article gave a definite edge to Hypercard since there were beautiful graphics mixed with text. Is this a shortcoming of Zoomracks?

By the way the author of Zoomracks is Paul Heckel - the same person who developed the Craig Language Translator and wrote "The Elements of Friendly Software Design" (This is from the article).

Dear sir.
I own an Atari 1040ST and I would like to try using it for
image processing in cardiology. I need a video digitizer which
will be able to digitize stop-frame video tape pictures (not
video camera), and be compatible with the video standards PAL,
NTSC, SECAM, colors and/or black and white. Apart from obtaining
the pictures on the monitor screen, I am interested in getting
numeric picture files of 8 bits for each pixel. I would
appreciate if you will be able to find out for me information on
the above subject, be it available commercial devices, electronic
kits, tested circuits in data sheet form or BITNET addresses of
ST users successfully employing such digitizers.
I am looking forward to your answer.

Sincerely yours

Dr. Ron Leor,
The Heart Institute,
Sheba Hospital, Tel Hashomer,
Tel Avive, ISRAEL.

Subject: INTERRUPT PROCESSING
To: info-atari16@score.stanford.edu

How do you disable and enable interrupts from
1. The keyboard?
2. The SIO port?

In the documentation at my disposal (Mark Williams C and Abacus)
I can find the following table under Jdisint:

Interrupt # event
0 I/O port bit 0
1 I/O prot bit 1
2 I/O port bit 2
3 I/O port bit 3
4 Timer D
5 Timer C
6 I/O port bit 4
7 I/O port bit 5
8 Timer B
9 sender error
10 sender buffer empty
11 receive error
12 receive buffer full
13 Timer A
14 I/O port bit 6
15 I/O port bit 7

Half of these are self explanatory, but the other half requires
a mapping to atari st hardware events. Would someone be kind
enough to inform me what events are represented by I/O port bits 0-7 in
the atari 1040 ST? I presume that one of these represents a
keyboard interrupt and another an SIO interrupt; otherwise
I really need help!

Thanks,

Jonathan Nagy

> Anyone out there know a company that sells a prototype
> board for the ST cartridge slot. Any info on physically
> plugging into the cartridge slot would be appreciated.

I recently built a battery-backed real-time clock and a four
channel A/D converter to plug into my cartridge port. I bought
the board from,

Douglas Electronics
718 Marina Blvd.
San Leadro, CA 94577
(415) 483-8770

The board fits perfectly into the cartridge slot. It has holes
spaced at 0.10 inches, 20 rows by 30 columns, with 8 rows dedi-
cated for power and ground buses. The part number is 33-DE-40,
costs $10.00, they'll ship it however you want, and they accept
MC and VISA. I have nothing to do with this outfit other than
being a satisfied customer.

Subject: 520ST Jittery Monitor Woes
To: info-atari16@score.stanford.edu

I consider this problem to be minor, but I thought I'd see if anyone
has had a similar experience. After my computer (520 ST) has been
on for 1 to 1.5 hours, the *low resolution* display begins to get
jittery. It starts out very mild (one or two scan lines misplaced

a little) and then regresses to the point that I can hardly stand
to look at it. If I switch to medium resolution, the problem
disappears. Or, if I turn the computer off for a minute (just the
computer, not the monitor or drive) then turn it back on, the
display will be normal again for a while. Then the whole sequence
repeats. It's been this way for a long, long time, but I didn't care
too much because I almost always use medium resolution (the problem
never occurs in this mode). I just recently acquired some neat
(low resolution mode) games so now it's starting to annoy me. Although
the computer is properly ventilated, my guess is that something is
overheating. Any other ideas??????

I have been using a handy utility called PicSwitch to convert Mac, Amiga and
Mono ST pictures (Degas, NeoChrome) to be viewable on my RGB, It's Shareware,
I believe, so I'd be happy to send you a copy if you'd like.

Subject: Zoomracks (i.e. Hypercard's predecessor?)
To: info-atari16@score.stanford.edu

I was just reading this quarter's STart magazine (Wint87), and came across an
article on Zoomracks - an ST product which sounds a lot like Hypercard for the
Mac. One major difference being that Zoomracks has been around for 3 years.

The article is interesting. If anyone has used the product, perhaps they
can post their views.

Why hasn't this product come to light earlier? One thing I did notice was
that the screens used in this article gave a definite edge to Hypercard
since there were beautiful graphics mixed with text. Is this a shortcoming
of Zoomracks?

By the way the author of Zoomracks is Paul Heckel - the same person who
developed the Craig Language Translator and wrote "The Elements of
Friendly Software Design" (This is from the article).

Dear sir.
I own an Atari 1040ST and I would like to try using it for image processing in cardiology. I need a video digitizer which will be able to digitize stop-frame video tape pictures (not video camera), and be compatible with the video standards PAL, NTSC, SECAM, colors and/or black and white. Apart from obtaining the pictures on the monitor screen, I am interested in getting numeric picture files of 8 bits for each pixel. I would appreciate if you will be able to find out for me information on the above subject, be it available commercial devices, electronic kits, tested circuits in data sheet form or BITNET addresses of ST users successfully employing such digitizers.
I am looking forward to your answer.

Sincerely yours

Dr. Ron Leor,
The Heart Institute,
Sheba Hospital, Tel Hashomer,
Tel Avive, ISRAEL.

OK. We (Athabasca University Computing Services) got our kit sometime
in September or October of 1986. I cannot speak for later Developer's
Kits than that. Honestly, I can only say that it was better than the
```

doc's I got from DRI when I first got CP/M - you old CP/M hackers out there can go from there ;-) For the rest of you, I can only say that reading and using the docs supplied was a little like playing Adventure - except that it's a lot slower and more frustrating. If some kind soul hadn't posted the "Proffesional GEM" (by Tim Oren) stuff to the net, and if I hadn't gone out and bought the MWC package, I don't think we would have ever done anything interesting with our 1040's. Sigh.

To start, there is a very large stack of paper, perhaps 5 or so inches thick (8.5" x 11" paper, double sided xerographic copies). I have it in three two-inch ring binders, and they are _full_. The quality of the reproduction is a little disappointing, but readable; the only frustration is that occasionally the copies are skewed so that some text falls off the edge of the page. This is not too much of a problem.

Volume 1: (about 580 pages)

a nondisclosure agreement

some waffle about 'please write portable code in case we decide to fool around with the hardware specs'.

some blank SPR (bugreport) forms. If I had used these things, I would have needed 20 times as many as are supplied.

keycode table errata list

writeup on the ACSI buss (interface & protocol) [hard disk port] + listing of (23Jul85) hard disk driver as example of ACSI stuff.

Introduction to Gem Programming (DRI): this is the IBM version, it does not exactly conform to the supplied software. Pretty obscure in places, but valuable to the initiated.

GEM Programmer's Guide - Vol 1, VDI (DRI): a description of the low-level graphics primitives in _excruciating_ detail, plus a little bit about the non-existant GDOS, and some very useful info on font files. This is a reference work, very few examples of actual use. It is pretty complete, but again more useful to the initiated than the novice.

GEM Programmer's Guide - Vol 2, AES (DRI): a description of the higher level stuff in GEM, such as the window and event libraries, menus, manipulation of icons, et c., et c. Again, a reference document. Lots of info if you know what you're looking for, but not a tutorial at all.

Volume 2: (about 400 pages)

GEM DOS 1.0 specs (DRI): calling conventions & stuff. Readable, useful. Includes C bindings.

Hitchhiker's Guide to the BIOS: for a change, a really pleasant
piece of doc on the BIOS - has a few errors, and can get
a little self-indulgent (and obscure), but still a solid
source of info on the low-level stuff. Lots of neat
stuff on how booting is performed, & c.

Line-A Technical Reference Manual: detailed discussion of the
bit blt code, parameters, & how to call it. rather
confusing organization, and again the attempts at humour
can be irritating on the 500th reading. Not for the
faint of heart.

Intelligent Keyboard (IKBD) Protocol: really good writeup of
how the mouse, joystick, and keyboard work. I wish _all_
the docs were this good.

BIOS listing: a listing of the ST's BIOS. I sure wish this
had been the listing output by the assembler, as it is
there is no symbol table or hex listing, so it's a pain
to follow the code around. But handy when you have to
know _exactly_ how something works.

Volume 3: (about 600 pages)

DRI 'C' Language Programming Guide for CP/M 68K: this is the doc
for the (in)famous Alcyon C. Ugh, blech, ack phfft! I
cannot say anything good about the thing.

DRI CP/M 68K Operating System Programmer's Guide: this is the most
useless thing you could imagine. It has nothing to do with
TOS at all. The only good thing is that it explains a few
things about SID, the linker, and the assembler. Otherwise
it only confuses anyone who doesn't realize it has nothing
to do with using the ST.

Kermit User's Guide, Fourth Edition: I never used this & have
no intention of ever using it. We have ZMODEM :-). But
it looks well enough written.

Engineering Hardware Specification of the Atari ST Computer System:
A good quick overview of the ST. Terse and pithy.

Western Digital WD1770/1772 5-1/4" Floppy Disk Controller/Formatter:
This is a typical engineering component data-book sort
of description; very, very complete and includes
examples of anything you would need to know, and a lot
of stuff you don't need to know (like pinouts). Aimed
at engineers.

MIDI Specification 1.0: Now this is a real prize. It's
exactly one page long, and says 'for more information,
please contact...' and gives the address of the IMA.
Really! Somebody was working overtime on this, I'm sure.

(Untitled): long, unreadable & boring description of the STC504
and SMM804 printers. Typical Japanese-style (no racial
slurs intended) printer manual organization of jillions
of tables, everything cross referenced to something on
another page. NO examples.

(Untitled): etch masks and schematics for building ROM
cartridges, plus mechanical drawing of connectors. OK,
I guess; my ex-wife, who does this sort of thing for a
living, wasn't very impressed. Me, I do software :-)

United Technologies/Mostek MK68901 Multi-function Peripheral:
Just like the WD1772 writeup. More stuff than you ever
wanted to know, or thought possible.

Schematic Diagram: a schematic for a 520ST. two 14" x 11"
sheets, hard to read, and not the best organization.
Still, it's enough to figure out things like 'which bit
in the 68901 do I fiddle to assert DTR on the serial
port' and that sort of thing.

--

And that brings us to the end of the stack of paper. In summary,
there's a whole lot of information here, but d*mned little guidance.
It really needs something like the "Proffesional GEM" series to get
the newcomer started - as it is you're so busy reading about every leaf
on every tree you have no idea at all what the forest looks like ;-) !

Also, there's no master index. Some of the separate documents are
indexed, but you have to know which one to look in first, which means
plowing through all 1600 pages at least once. You can bet that takes
some time...

"And now, Ladees and Gennelmun, in the center ring! It boots, and who
knows, maybe you can even do developement with it! (I sure had a h*ll
of a time, though.) The amaaazing Atari Developer's Software Toolkit!"
This sorry collection comes on 5 single-sided flops. I hereby list
them:

Flop 1 - C Compiler, Assembler, and .H files

The dreaded Alcyon C compiler. At the risk of redundancy, let
me restate my earlier comments: Ack phfft!! The poorest commercial C
compiler you ever met. Generates assembly output, useful for deciding
what kind of bugs it has introduced into your code this time around...
Slow, buggy, and not even full K&R much less ANSI. Daryl (the other
hacker in this shop) struggled with it for about 3 months and even got
some stuff to work :-) but I wouldn't touch it with a barge pole.

Flop 2 - Linker, Libraries, Thing to make Linker output executable

An amazingly slow linker. Libraries with some *nasty* bugs in
them. And a hack to get CP/M 68K executables to run under TOS. Gag me
with a spoon...

Flop 3 - Utilities: Debugger, Kermit, and some C runtime environment asm code

I sort of like SID, probably because I used it under CP/M so much. We never did use the supplied KERMIT. The other stuff was ok, but pretty ho-hum; no RAMdisk or anything remotely useful like that. The APSKEL.C (application skeleton - sort of a 'hello world' for GEM) was a good thing, although I think that programmer should be shot; his style makes my teeth ache.

Flop 4 - Icon Editors and Resource Construction Set, plus Doodle C source

Again, having source code as an example is a really fine thing. The only problem is that since it's designed to compile under Alcyon, you spend most of your time wondering "now why is he doing that?" instead of seeing "oh, so that's how you do <arbitrary GEMish thing>". The RCS is useful and pretty completely undocumented (there are a few hints in 'Introduction to GEM Programming' (Vol 1), but nothing like a real write up anywhere). To an experienced GEM hacker, of course, it's all pretty obvious. Took me a long time. Of the two supplied icon editors, only one is useful (the other is just too primitive), and even it has a few annoying bugs - I could never get it to save both an icon and it's mask in one file... but maybe that's me & not it. Bets, anyone?

Flop 5 - Emacs, various source and a doc file

Well, lessee - Doodle (again), a demo of how to use the forms library, a copy of a very early Mark Williams Co. emacs, and a tutorial doc on how to read/write floppies by directly twiddling the WD1772 (which, by the way, appears in printed form in the pile of paper...). The emacs I considered a great thing, since I use it on Un*x all the time (I'm in it now, as a matter of fact). The rest is nice to have, although my criticism of impenetrable Alcyon style still holds. To bad they didn't give source for the emacs, though.

--

And that's it. There's no shell supplied, instead they have an incredibly klugey 'batch processor' to invoke the various & sundry programmes required to do anything interesting like, say, getting a compile-and-link done. No RAMdisk to help speed things up. The real prizes are the ICED icon editor, the RCS, and the emacs. The Alcyon C compiler, the assembler, linker, and libraries are a disaster. The debugger is ok but primitive. The source code is good but obscure because of the Alcyon bug-workarounds (or lack-of-feature workarounds).

Now, having waded through all this p*ssing and moaning, what would I recommend instead? For a start, go out and get a copy of the Mark Williams C package. Not too many bugs, nice Un*x compatability libraries, ok shell & tools (you know, stuff like egrep and tail and wc), source for an emacs, pretty good (but not quite complete) GEM and VDI docs, and a RAMdisk. In all, not a bad package deal. I have hacked on it pretty heavily and like it well enough. Secondly, get a subscription to START Magazine (with the disks!). Thirdly, get ahold

of the Proffesional GEM series by Tim Oren - this is a must have.
I don't know about a Resource Construction Set, though; we're using DRI
RCS 2.0, but maybe you can get a copy of the KUMA version. And I'm
still looking for a really good icon editor. I also recommend GULAM,
and the ZMODEM that was posted about 6 months ago. Or Uniterm - that's
a good solid piece of freeware too.

Short list of things to stay away from: any of the bloody useless
Abacus Software books (except maybe vol 13, "ST Disk Drives", which is
almost useful). These things are just copies of the DRI stuff, with
gratuitous errors added to avoid copyright infringement :-(

Any other suggestions from the other hackers out there? I want to get
down off this soapbox, my feet are tired :-)

[]

I wonder: is the 18 inch limit on the length of the cable connecting
the ST to the Atari SH204 hard disk (stated in the user manual) the
real technical limit? Would be very nice to have a, say, 3 feet cable.
(I hate fan and motor noise.)

Does anybody have a disassembly of AHDI.PRG? I have a strange bug, and
suspect that AHDI.PRG fiddles with high RAM. Could that be? Is there
an alternative driver program for the Atari HD?

- Moshe Braner

PS: how can I persuade PC-Ditto to read partitions D: and E: from inside
MS-DOS? I am trying out PCD 3.0 on 1040ST, mono, SH204 HD, and _did_ put
"device=pc_dhd.sys" at top of config.sys. "Dir d:" prints either garbage or
an empty list of files. The PCD docs say that reformatting the HD is _not_
required (unless you want to autoboot MS-DOS from the HD, in which case you
must let MS-DOS reformat partition C:). Partition C reads OK (and I did
not reformat it).

Subject: Print Master icons -- what is PD?
To: info-atari16@score.stanford.edu

It is clear from recent mail that I have received that commercial
PrintMaster are getting mixed up with PD icons. Since I run a BBS this
is something I have to be careful about, and I thought it might help to
identify the three commercial libraries that I am familiar with. Here
is a list of the first 4 icons in the three library disks published by
Unison World. If you have a library that begins with these icons, it is
probably pirated.

PrintMaster, usually called SLIB or STANDARD library:
Christmas Tree, Menorah, Cake, Easter

Art Gallery I, usually called ULIB
Santa, Snowflake, Star of David, Black Cat

Art Gallery II, usually called GALLERY2
Snow Scene, Conductor, Crown of Thorns, I Forget

I don't have the commercial Fonts and Borders disk, so I can't comment
on what is PD in that area.

To tell the truth, the Art Gallery series is pretty crummy, and the PD
libraries are better. I bought them cheap and still felt ripped off.
However, copyright is copyright.

Yep, I got the Zoomracks II version while at Comdex over a year
ago...it lets you store degas pictures as part of your
datasets...among other features.
>
>Why hasn't this product come to light earlier? One thing I did notice was
>that the screens used in this article gave a definite edge to Hypercard
>since there were beautiful graphics mixed with text. Is this a shortcoming
>of Zoomracks?

Yes, and no...It depends upon how much you really depend on graphics.
I like the Zoomracks approach because it got more information on the
screen at once (although it looks like a mess if you were expecting
graphics.) But then, I also am the type of person that turns off my
icons on the ST display and just use narrow vertical boxes of text
file names for my desktop view (to see more files). From a programmers
point of view, I still have yet to come up with a use for hypercard
(I've played with it and am not impressed enough to upgrade my wifes
Mac just for that). Zoomracks II seems to have a lot of power and
macro programmability to it, but give a person a good database, a good
spreadsheet, and a good word processor and they will probably be more
happy in the long run.

I know that a lot of the MCC people down in Texas are doing Hypertext
based applications (which hypercard was derived from). It would be
nice if they tried porting some of their stuff over to the ST's (they
are currently SUN and Symbolics based.) I think the Mega's would make
a nice engine for their needs (and things like the ABAQ would fit into
their longer term AI stuff where they are really going to need the
horsepower). If I remember right, MCC stands for Micro-electronics
Computer Consortium and is a research organization funded by 20 or so
large companies in the US to develop new technology in a variety of
computer and IC design specific areas...

From: ptsfa!well!dsmall@tis.llnl.gov (David Small)
Subject: Re: speeding floppies?
To: info-atari16@score.stanford.edu

In the referenced article, there's much discussion about speeding
up floppies from Michael Stein.

There's no point in using a disk with interleave on it on the ST; the
ST is more than capable of 1:1 reads and writes. Since the ultimate
limiting factor is the head rubbing against the media at a certain speed,
and the ST is doing r/w as fast as physically possible, there's no
possible gain there.
It is dangerous to remove the seek verify bit in the manner you have.
Let's say you step to a new track. The head rattles back and forth
awhile as it settles. During that time it is reading well enough to
return track dta to the controller, yet the head is still wobbling. If you
try a sector write, which lasts 16 msec, during this time, it's written in
a yo-yo pattern on the disk -- and is often unreadable the next time.
This comes from hard experience; I did this on the Magic Sac Motivator, and
could consistently kill the first sector of each track. Weird, but true.
You're right that a full disk rev is saved. A better way is to just twist
the track two sectors around, leaving one sector (#9 or 10) for the settle
time and one sector (#8 or 9) for the seek verify. Then you don't lose any
time at all track to track, and keep full compatability with unmodified
ST's. That's how we did Twister.
As for using the index pulse as the delay time for seek, well, maybe. On
9 sector tracks you'll get away with it.. remember, 16.667 millisec per sector.
On 10 sector tracks you won't, there is no room. But worse, the step only
happens on the next-sector-read command, which may take awhile to
happen, all of which time the disk is spinning.
Since you're stuck with 30 msec head settle, and lots of machine have
seek-with-verify, I think it's the optimal solution to twist the track by 2.
You just can't physically get data off multiple tracks any quicker without
speeding up the RPMs of the drive.

.. perhaps we should plug it into a 220 Volt outlet?

> (Just the facts, ma'am)
> Ron

OK. We (Athabasca University Computing Services) got our kit sometime
in September or October of 1986. I cannot speak for later Developer's
Kits than that. Honestly, I can only say that it was better than the
doc's I got from DRI when I first got CP/M - you old CP/M hackers out
there can go from there ;-) For the rest of you, I can only say that
reading and using the docs supplied was a little like playing Adventure
- except that it's a lot slower and more frustrating. If some kind

soul hadn't posted the "Proffesional GEM" (by Tim Oren) stuff to the net, and if I hadn't gone out and bought the MWC package, I don't think we would have ever done anything interesting with our 1040's. Sigh.

To start, there is a very large stack of paper, perhaps 5 or so inches thick (8.5" x 11" paper, double sided xerographic copies). I have it in three two-inch ring binders, and they are _full_. The quality of the reproduction is a little disappointing, but readable; the only frustration is that occasionally the copies are skewed so that some text falls off the edge of the page. This is not too much of a problem.

Volume 1: (about 580 pages)

a nondisclosure agreement

some waffle about 'please write portable code in case we decide to fool around with the hardware specs'.

some blank SPR (bugreport) forms. If I had used these things, I would have needed 20 times as many as are supplied.

keycode table errata list

writeup on the ACSI buss (interface & protocol) [hard disk port] + listing of (23Jul85) hard disk driver as example of ACSI stuff.

Introduction to Gem Programming (DRI): this is the IBM version, it does not exactly conform to the supplied software. Pretty obscure in places, but valuable to the initiated.

GEM Programmer's Guide - Vol 1, VDI (DRI): a description of the low-level graphics primitives in _excruciating_ detail, plus a little bit about the non-existant GDOS, and some very useful info on font files. This is a reference work, very few examples of actual use. It is pretty complete, but again more useful to the initiated than the novice.

GEM Programmer's Guide - Vol 2, AES (DRI): a description of the higher level stuff in GEM, such as the window and event libraries, menus, manipulation of icons, et c., et c. Again, a reference document. Lots of info if you know what you're looking for, but not a tutorial at all.

Volume 2: (about 400 pages)

GEM DOS 1.0 specs (DRI): calling conventions & stuff. Readable, useful. Includes C bindings.

Hitchhiker's Guide to the BIOS: for a change, a really pleasant piece of doc on the BIOS - has a few errors, and can get a little self-indulgent (and obscure), but still a solid source of info on the low-level stuff. Lots of neat stuff on how booting is performed, & c.

Line-A Technical Reference Manual: detailed discussion of the
bit blt code, parameters, & how to call it. rather
confusing organization, and again the attempts at humour
can be irritating on the 500th reading. Not for the
faint of heart.

Intelligent Keyboard (IKBD) Protocol: really good writeup of
how the mouse, joystick, and keyboard work. I wish _all_
the docs were this good.

BIOS listing: a listing of the ST's BIOS. I sure wish this
had been the listing output by the assembler, as it is
there is no symbol table or hex listing, so it's a pain
to follow the code around. But handy when you have to
know _exactly_ how something works.

Volume 3: (about 600 pages)

DRI 'C' Language Programming Guide for CP/M 68K: this is the doc
for the (in)famous Alcyon C. Ugh, blech, ack phfft! I
cannot say anything good about the thing.

DRI CP/M 68K Operating System Programmer's Guide: this is the most
useless thing you could imagine. It has nothing to do with
TOS at all. The only good thing is that it explains a few
things about SID, the linker, and the assembler. Otherwise
it only confuses anyone who doesn't realize it has nothing
to do with using the ST.

Kermit User's Guide, Fourth Edition: I never used this & have
no intention of ever using it. We have ZMODEM :-). But
it looks well enough written.

Engineering Hardware Specification of the Atari ST Computer System:
A good quick overview of the ST. Terse and pithy.

Western Digital WD1770/1772 5-1/4" Floppy Disk Controller/Formatter:
This is a typical engineering component data-book sort
of description; very, very complete and includes
examples of anything you would need to know, and a lot
of stuff you don't need to know (like pinouts). Aimed
at engineers.

MIDI Specification 1.0: Now this is a real prize. It's
exactly one page long, and says 'for more information,
please contact...' and gives the address of the IMA.
Really! Somebody was working overtime on this, I'm sure.

(Untitled): long, unreadable & boring description of the STC504
and SMM804 printers. Typical Japanese-style (no racial
slurs intended) printer manual organization of jillions
of tables, everything cross referenced to something on
another page. NO examples.

(Untitled): etch masks and schematics for building ROM cartridges, plus mechanical drawing of connectors. OK, I guess; my ex-wife, who does this sort of thing for a living, wasn't very impressed. Me, I do software :-)

United Technologies/Mostek MK68901 Multi-function Peripheral: Just like the WD1772 writeup. More stuff than you ever wanted to know, or thought possible.

Schematic Diagram: a schematic for a 520ST. two 14" x 11" sheets, hard to read, and not the best organization. Still, it's enough to figure out things like 'which bit in the 68901 do I fiddle to assert DTR on the serial port' and that sort of thing.

--

And that brings us to the end of the stack of paper. In summary, there's a whole lot of information here, but d*mned little guidance. It really needs something like the "Proffesional GEM" series to get the newcomer started - as it is you're so busy reading about every leaf on every tree you have no idea at all what the forest looks like ;-) !

Also, there's no master index. Some of the separate documents are indexed, but you have to know which one to look in first, which means plowing through all 1600 pages at least once. You can bet that takes some time...

"And now, Ladees and Gennelmun, in the center ring! It boots, and who knows, maybe you can even do developement with it! (I sure had a h*ll of a time, though.) The amaaazing Atari Developer's Software Toolkit!" This sorry collection comes on 5 single-sided flops. I hereby list them:

Flop 1 - C Compiler, Assembler, and .H files

The dreaded Alcyon C compiler. At the risk of redundancy, let me restate my earlier comments: Ack phfft!! The poorest commercial C compiler you ever met. Generates assembly output, useful for deciding what kind of bugs it has introduced into your code this time around... Slow, buggy, and not even full K&R much less ANSI. Daryl (the other hacker in this shop) struggled with it for about 3 months and even got some stuff to work :-) but I wouldn't touch it with a barge pole.

Flop 2 - Linker, Libraries, Thing to make Linker output executable

An amazingly slow linker. Libraries with some *nasty* bugs in them. And a hack to get CP/M 68K executables to run under TOS. Gag me with a spoon...

Flop 3 - Utilities: Debugger, Kermit, and some C runtime environment asm code

I sort of like SID, probably because I used it under CP/M so much. We never did use the supplied KERMIT. The other stuff was ok, but pretty ho-hum; no RAMdisk or anything remotely useful like that.

The APSKEL.C (application skeleton - sort of a 'hello world' for GEM) was a good thing, although I think that programmer should be shot; his style makes my teeth ache.

Flop 4 - Icon Editors and Resource Construction Set, plus Doodle C source

Again, having source code as an example is a really fine thing. The only problem is that since it's designed to compile under Alcyon, you spend most of your time wondering "now why is he doing that?" instead of seeing "oh, so that's how you do <arbitrary GEMish thing>". The RCS is useful and pretty completely undocumented (there are a few hints in 'Introduction to GEM Programming' (Vol 1), but nothing like a real write up anywhere). To an experienced GEM hacker, of course, it's all pretty obvious. Took me a long time. Of the two supplied icon editors, only one is useful (the other is just too primitive), and even it has a few annoying bugs - I could never get it to save both an icon and it's mask in one file... but maybe that's me & not it. Bets, anyone?

Flop 5 - Emacs, various source and a doc file

Well, lessee - Doodle (again), a demo of how to use the forms library, a copy of a very early Mark Williams Co. emacs, and a tutorial doc on how to read/write floppies by directly twiddling the WD1772 (which, by the way, appears in printed form in the pile of paper...). The emacs I considered a great thing, since I use it on Un*x all the time (I'm in it now, as a matter of fact). The rest is nice to have, although my criticism of impenetrable Alcyon style still holds. To bad they didn't give source for the emacs, though.

--

And that's it. There's no shell supplied, instead they have an incredibly klugey 'batch processor' to invoke the various & sundry programmes required to do anything interesting like, say, getting a compile-and-link done. No RAMdisk to help speed things up. The real prizes are the ICED icon editor, the RCS, and the emacs. The Alcyon C compiler, the assembler, linker, and libraries are a disaster. The debugger is ok but primitive. The source code is good but obscure because of the Alcyon bug-workarounds (or lack-of-feature workarounds).

Now, having waded through all this p*ssing and moaning, what would I recommend instead? For a start, go out and get a copy of the Mark Williams C package. Not too many bugs, nice Un*x compatability libraries, ok shell & tools (you know, stuff like egrep and tail and wc), source for an emacs, pretty good (but not quite complete) GEM and VDI docs, and a RAMdisk. In all, not a bad package deal. I have hacked on it pretty heavily and like it well enough. Secondly, get a subscription to START Magazine (with the disks!). Thirdly, get ahold of the Proffesional GEM series by Tim Oren - this is a must have. I don't know about a Resource Construction Set, though; we're using DRI RCS 2.0, but maybe you can get a copy of the KUMA version. And I'm

still looking for a really good icon editor. I also recommend GULAM, and the ZMODEM that was posted about 6 months ago. Or Uniterm - that's a good solid piece of freeware too.

Short list of things to stay away from: any of the bloody useless Abacus Software books (except maybe vol 13, "ST Disk Drives", which is almost useful). These things are just copies of the DRI stuff, with gratuitous errors added to avoid copyright infringement :-(

Any other suggestions from the other hackers out there? I want to get down off this soapbox, my feet are tired :-)

To: info-atari16@score.stanford.edu

[]

I wonder: is the 18 inch limit on the length of the cable connecting the ST to the Atari SH204 hard disk (stated in the user manual) the real technical limit? Would be very nice to have a, say, 3 feet cable. (I hate fan and motor noise.)

Does anybody have a disassembly of AHDI.PRG? I have a strange bug, and suspect that AHDI.PRG fiddles with high RAM. Could that be? Is there an alternative driver program for the Atari HD?

- Moshe Braner

PS: how can I persuade PC-Ditto to read partitions D: and E: from inside MS-DOS? I am trying out PCD 3.0 on 1040ST, mono, SH204 HD, and _did_ put "device=pc_dhd.sys" at top of config.sys. "Dir d:" prints either garbage or an empty list of files. The PCD docs say that reformatting the HD is _not_ required (unless you want to autoboot MS-DOS from the HD, in which case you must let MS-DOS reformat partition C:). Partition C reads OK (and I did not reformat it).

Subject: Print Master icons -- what is PD?
To: info-atari16@score.stanford.edu

It is clear from recent mail that I have received that commercial
PrintMaster are getting mixed up with PD icons. Since I run a BBS this
is something I have to be careful about, and I thought it might help to
identify the three commercial libraries that I am familiar with. Here
is a list of the first 4 icons in the three library disks published by
Unison World. If you have a library that begins with these icons, it is
probably pirated.

PrintMaster, usually called SLIB or STANDARD library:
Christmas Tree, Menorah, Cake, Easter

Art Gallery I, usually called ULIB
Santa, Snowflake, Star of David, Black Cat

Art Gallery II, usually called GALLERY2
Snow Scene, Conductor, Crown of Thorns, I Forget

I don't have the commercial Fonts and Borders disk, so I can't comment
on what is PD in that area.

To tell the truth, the Art Gallery series is pretty crummy, and the PD
libraries are better. I bought them cheap and still felt ripped off.
However, copyright is copyright.

>Mac. One major difference being that Zoomracks has been around for 3 years.
Yep, I got the Zoomracks II version while at Comdex over a year
ago...it lets you store degas pictures as part of your
datasets...among other features.
>
>Why hasn't this product come to light earlier? One thing I did notice was
>that the screens used in this article gave a definite edge to Hypercard
>since there were beautiful graphics mixed with text. Is this a shortcoming
>of Zoomracks?

Yes, and no...It depends upon how much you really depend on graphics.
I like the Zoomracks approach because it got more information on the
screen at once (although it looks like a mess if you were expecting
graphics.) But then, I also am the type of person that turns off my
icons on the ST display and just use narrow vertical boxes of text
file names for my desktop view (to see more files). From a programmers
point of view, I still have yet to come up with a use for hypercard
(I've played with it and am not impressed enough to upgrade my wifes
Mac just for that). Zoomracks II seems to have a lot of power and
macro programmability to it, but give a person a good database, a good
spreadsheet, and a good word processor and they will probably be more
happy in the long run.

I know that a lot of the MCC people down in Texas are doing Hypertext
based applications (which hypercard was derived from). It would be
nice if they tried porting some of their stuff over to the ST's (they
are currently SUN and Symbolics based.) I think the Mega's would make
a nice engine for their needs (and things like the ABAQ would fit into
their longer term AI stuff where they are really going to need the
horsepower). If I remember right, MCC stands for Micro-electronics
Computer Consortium and is a research organization funded by 20 or so
large companies in the US to develop new technology in a variety of
computer and IC design specific areas...

From: ptsfa!well!dsmall@tis.llnl.gov (David Small)
Subject: Re: speeding floppies?
To: info-atari16@score.stanford.edu

In the referenced article, there's much discussion about speeding
up floppies from Michael Stein.

There's no point in using a disk with interleave on it on the ST; the
ST is more than capable of 1:1 reads and writes. Since the ultimate
limiting factor is the head rubbing against the media at a certain speed,
and the ST is doing r/w as fast as physically possible, there's no
possible gain there.
It is dangerous to remove the seek verify bit in the manner you have.
Let's say you step to a new track. The head rattles back and forth
awhile as it settles. During that time it is reading well enough to
return track dta to the controller, yet the head is still wobbling. If you
try a sector write, which lasts 16 msec, during this time, it's written in
a yo-yo pattern on the disk -- and is often unreadable the next time.
This comes from hard experience; I did this on the Magic Sac Motivator, and
could consistently kill the first sector of each track. Weird, but true.
You're right that a full disk rev is saved. A better way is to just twist
the track two sectors around, leaving one sector (#9 or 10) for the settle
time and one sector (#8 or 9) for the seek verify. Then you don't lose any

>the point-blank assertion that FOLDRXXX.PRG was designed to work with ANY
>POSSIBLE version of TOS. Would an Atari spokesperson care to post a COMPLETE,
>AUTHORITATIVE answer?

I am not from Atari, but the answer that I believe to be the correct one is this: As of the time that FOLDRXXX was written, there had been only the listed versions (dates) of the ROMs created by Atari. A decision had been made within Atari to put a pointer to this elusive location (the list pointer) into all future ROM versions at a specific location. Therefore, if FOLDRXXX cannot find the date of the ROM in the table built into it, it assumes it to be a ROM that follows the new conventions, and uses the pointer from the ROM instead.

That is the mechianism that (name witheld) at Atari has assured me is the way that FOLDRXXX will work with ALL future ROMs that Atari produces. Non-atari ROMs may not follow this convention. I have tested this assertion using a mechanism I'm not able to divuldge at this time to try this out with a version of TOS loaded at other locations, and FOLDRXXX works fine with them as well (so it uses an offset from SYSBASE, not a fixed ROM address).

Now, all atari has to do is to publicly document these offsets so that programs that use the important information in these places can work on all future ROM versions.

The desired locations are:

The GEMDOS current process pointer
The GEMDOS buffer pool pointers
The BIOS/XBIOS jump tables for stream devices
The Mouse Hidden / displayed counter
The shift state mask (since it is not kosher to use Kbshift() from an interrupt hander)

Allan? Neil? Any comments on these from anyone at Atari?

dag

1130. BMS Boards, IMI and MiniScribe mechanisms

Newsgroup: comp.sys.atari.st
Date: 1988-01-12 03:57:59 UTC
From: weaver@tut.cis.ohio-state.edu
Message-ID: <4245@tut.cis.ohio-state.edu>
Source record: 255130

A few weeks (months?) back I posted some of my triumphs and
tribulations of creating a hard drive for my 520ST, and I thought some
of you doing the same might like to hear about it. (If not, hit 'n'.)

The IMI drives from the Corvus Systems' network boxes DID work
with the drives. They behave similarly to the standard st506 drive, but
these wierdos have 6 heads and format to about 15Mb apiece.

Fortunately a friend provided me with a MiniScribe mechanism that
formats to about 21Mb, which was nicer. But, I got greedy and wanted
to hook up my Miniscribe and one of the two IMIs. Well, after getting
a three-way cable from another friend, I attempted to hook the two together.
Well, to those that have IMI drives, don't try to hook them to a Miniscribe
on the same BMS controller board. It will work OK for awhile, but event-
ually trash the filesystem on the Miniscribe. I think that somewheres
these boys are electrically incompatible, or perhaps I had a bad three-way
cable. In any event I went with a simple one-drive system.

Since I have had no problems. I took the drive home with me
during winter break, forgot to park the heads (dummy) and didn't even
have the drive bolted down inside the box, and the things still somehow
survived. Call it karma, or whatever, but now its bolted down.

Thinking about buying a BMS? DO IT. If you can cough up the
$250 for the boards, can find a cheap drive mechanism and a power supply
(and a fan and box, but not to get up and running) go for it. Spending
$500-$700 on a turnkey from Atari, ICD or Supra isn't worth it if you
are willing to take a few chances... and save about half.

I just read the article about the Atari laser being available
retail at last--$1600 without on-board memory, fonts or CPU? Give it
up. You can get an Okidata for ~$1300... or better deals on PS printers
(non-Apple), while not at $1600, but with PS fonts and a CPU. Atari
better get real or they can forget it... really. I like Atari and all,
I will keep my ST, but my next computer will be from Apple. Sit down and
use a Mac II folks... you'll see a real computer. Nothing short of a
Sun 3/50 compares. You can argue "Multi-tasking" until Warner buys back
Atari and nothing will happen; for me, its Macs and UNIX in the future.
Not GEM, GemDog, AmigaDog or Intuition.

Off the soapbox...

We are huh? Right now I'm cooking dinner, typing on my computer and
listening to Prairie Home Companion on the radio. Sounds like multi-tasking
to me.

Don't forget that users who are running a single program could very well
be multi-tasking and not know it. For instance, color-cycling in
Graphic Craft spawned a subtask and operated independently. I believe that
Word Perfect's printer module is a separate program from the editor, at
least on the Amiga.

Pinouts on chips are not exactly free; they have a definite
manufacturing cost and per-connection reliability implications.
Engineers spend quite a bit of time juggling this scarce and valuable
resource (the pins) amongst all the possible things that they might
wish to ship in and out of the package. Hence all those bl**dy
multiplexed address/data schemes on cpu's (almost anything from Intel
last time I looked), multiplexed addresses on DRAMS, kluges to
redefine pins according to system configuration (Intel again, at
least on the 808[68] parts), and ghods know how many other egregious
hacks over the years. I mean, most engineers understand the KISS*
princple, and they don't design these horrible interfaces just for
the joy of complexity [well, most of them, anyway; I have dark
suspicions...].

So let's not be _too_ critical of Jay - your other examples were
much more convincing. My pet peeve is that the Atari people didn't
put a base-and-limit register into the big glue chip that controls
the memory array(s) on the ST. If I had base and limit registers, I
could get true, transparent multitasking up on the ST (which, of
course, Dave Meile could ignore; that's his privilege).

I think you're confusing interrupt processing with full multitasking. One
question you can ask yourself is: Can I run more than one program from the
same microprocessor? Or can I interchange programs between processors?
The answer: NO. Each chip is only capable of dealing with one task at a time,
and only a task specific to that chip. A real multitasking machine can have
the microprocessor (e.g. 68000) deal with more than one task on a revolving
basis, using priorities to see who gets more time, without having to wait for
each task to finish completely before starting the next one. If the computer
isn't too slow or weighted down (with tasks), this can appear to the user as if
each task is running at exactly the same time.

years.
If you want to call interrupt processing multitasking, then of course computers
have had it for many years, but it definitely isn't the kind that's going to,
by itself, allow you to run more than one of your favorite applications at the
same time.

There are at least two alternatives; the Supra driver and the ICD
driver. Both have been freely distributed on Compuserve.

> PS: how can I persuade PC-Ditto to read partitions D: and E: from inside

> not reformat it).

From messages on Compuserve, there are apparently some fields in the
boot sector that are "don't care" to the Atari driver, but are looked at
by IBM drivers. Avant-garde is distributing a patch program via Compuserve
(and presumably others) that zaps these fields from the garbage that they
are left at by the Atari formatter into something that MS-DOS approves of.

We are huh? Right now I'm cooking dinner, typing on my computer and listening to Prairie Home Companion on the radio. Sounds like multi-tasking to me.

Don't forget that users who are running a single program could very well be multi-tasking and not know it. For instance, color-cycling in Graphic Craft spawned a subtask and operated independently. I believe that Word Perfect's printer module is a separate program from the editor, at least on the Amiga.

Pinouts on chips are not exactly free; they have a definite
manufacturing cost and per-connection reliability implications.
Engineers spend quite a bit of time juggling this scarce and valuable
resource (the pins) amongst all the possible things that they might
wish to ship in and out of the package. Hence all those bl**dy
multiplexed address/data schemes on cpu's (almost anything from Intel
last time I looked), multiplexed addresses on DRAMS, kluges to
redefine pins according to system configuration (Intel again, at
least on the 808[68] parts), and ghods know how many other egregious
hacks over the years. I mean, most engineers understand the KISS*
princple, and they don't design these horrible interfaces just for
the joy of complexity [well, most of them, anyway; I have dark
suspicions...].

So let's not be _too_ critical of Jay - your other examples were
much more convincing. My pet peeve is that the Atari people didn't
put a base-and-limit register into the big glue chip that controls
the memory array(s) on the ST. If I had base and limit registers, I
could get true, transparent multitasking up on the ST (which, of
course, Dave Meile could ignore; that's his privilege).

I think you're confusing interrupt processing with full multitasking. One
question you can ask yourself is: Can I run more than one program from the
same microprocessor? Or can I interchange programs between processors?
The answer: NO. Each chip is only capable of dealing with one task at a time,
and only a task specific to that chip. A real multitasking machine can have
the microprocessor (e.g. 68000) deal with more than one task on a revolving
basis, using priorities to see who gets more time, without having to wait for
each task to finish completely before starting the next one. If the computer
isn't too slow or weighted down (with tasks), this can appear to the user as if
each task is running at exactly the same time.

years.
If you want to call interrupt processing multitasking, then of course computers
have had it for many years, but it definitely isn't the kind that's going to,
by itself, allow you to run more than one of your favorite applications at the
same time.

There are at least two alternatives; the Supra driver and the ICD
driver. Both have been freely distributed on Compuserve.

> not reformat it).

From messages on Compuserve, there are apparently some fields in the
boot sector that are "don't care" to the Atari driver, but are looked at
by IBM drivers. Avant-garde is distributing a patch program via Compuserve
(and presumably others) that zaps these fields from the garbage that they
are left at by the Atari formatter into something that MS-DOS approves of.

Here's something I picked up on CIS, Dave Small says the version of software shipping with the Translator One (version 5.4) supports HFS. He also said that they haven't decided upon the upgrade policy for non-Translator owners yet, so to give them a week or so to settle down (and recover from the Translator trauma, I'm sure) and figure out what to do next.

-ravi

>From: rowley@ORVILLE.NAS.NASA.GOV (Karl Rowley)
Newsgroups: comp.sys.atari.st
Subject: Magic Sac works/doesn't work update

Message-ID: <8712101753.AA15437@orville.nas.nasa.gov>
Date: 10 Dec 87 17:53:25 GMT
Sender: daemon@ucbvax.BERKELEY.EDU
Organization: The ARPA Internet
Lines: 27

I have tried some more software with the Magic Sac.

Here is an updated list of software that seems to work with the Sac:
Finder 6.0
System 4.2
MacWrite 4.6
MacDraft 1.2a (although I have heard of problems with MacDraft)
MacDraw 1.9.5
Microsoft Excel 1.03 and 1.04
Microsoft Word 3.01
Versaterm 2.3
Binhex 5.0
MacPaint
LightSpeed C 1.02
Software that does not work:
Red Ryder 9.2
New Scrapbook DA (crashes at random times)
MacWrite 4.5 (use MacWrite 4.6 instead)
CricketDraw (requires 128K ROMs)
Hypercard 1.01 (needs 128K ROMs)
Multifinder

Does anyone have the Transverter, and would they care to comment on it?

Status: R

Maurice,

I got my Translator and thought I'd send you what I sent to Dave at CIS.
By the way, HD20 is on Macserve and Infomac as UTILITY-RAM-BASED-HFS.HQX.

'Lator,

Roger.

Dave,

I thought I ought to send out some preliminary comments on the new stuff. This may be kind of confused, because I'm just starting out with not only the translator but also Magic 5 and HFS as well.

First of all, the packaging is very nice. Makes friendly (and tasty) impression.

First, about Sac 5. The manual says that there's no RAM cache in 828K mode. But something is definitely faster. Used to be, if you had a file selector box and kept hitting "Drive," it would poll a disk each time. It took so long that I got in the habit of yanking out any disk I wasn't using. But now, the lists pop up out of RAM somewhere. It's nifty. And another thing. When I open a 15 page document in my word processor, the whole thing is in RAM; I can go to any part of it, and it pops up without a disk access, which never happended before. Is this some sort of cache? Since I have no hard disk, this is the main difference I see in 5.

Oh, except HFS. I got HD20 to work, and it's pretty much fun. It feels a lot more like a Mac this way. A couple of problems, though. One, I can't get it to boot with 4.0/5.4. It just crashes. It will boot with 3.2/5.3; then you can switch to 4.0/5.4. Which is all right, but not exactly the optimum . I definitely do not like 3.2/5.3, so I need to switch.

The other problem is that I'm having a little trouble with RamStart in HFS. Well, it works, but HFS seems to be picky about what folder the system files are in, which conflicts with the RamStart notion that you put files you want to copy in one folder. The solution would be to use the RamStart scripts, but I find that they bring the Mac (and me) down. So, the question: Have you (anybody?) gotten scripts to work with RamStart. I'll admit, this is kind of a silly issue; I don't need an HFS startup disk, but as you say in the manual, pushing the outer limits, breaking the sound barrier, et.al. I mean, who's going to use Finder 4.1 just because it works?

The Translator: easy to install, nice long cables, but the LED is too bright. (I'm a tough customer). Oh, yeah: it works. Although, to be frank, I'm a little disappointed that it's kind of slow. I mean, I realize that it has to be slower on Mac disks than Magic disks, and, like you say, it's intended only for import and export. The disappointing thing is that I was hoping to rid my world of the Mac/Magic disk duality, get rid of all my Magic disks and all those labels, and simplify my life. Instead, I've got Mac/Magic, 1s/2s, and MFS/HFS (I don't even want to THIMK about GEMDOS). But I guess I'll learn to cope; after all, I learned how to use long distance and airlines in the 1980's. Anyhow, it does work, and will come in quite handy.

Oh, one more thing. When I was first trying out the 'lator yesterday, I was get ting some real weird noises out of the disks drives, particularly the inner one, which has always been raucous. This was particularly true with Magic disks. Mac disks make another noise, but it's kind of a gentle flutter. This was more spastic. But today, it seems to be quiet again.

OK, that's all. I'll be sure to let you if anything interesting happens when I try out some of the formatters, copiers, what not. Quite a relief to have the thing in hand (a relief for both of us, no doubt).

Cheers,

*Roger

****

I have the Magic Beep program and the Driver 4.33 update now, thanks to Jon Dunn. If you are interested, I will send it to you.

+Any suggestions? It seems so pointless to have to doubleclick the
+@#$% icon every time.
[return address omitted]

I'm not sure how many times this
has to be posted before people start
listening, but I'll try again...

Programs executed at boot-up from the \auto folder are executed before GEM is initialized. You cannot use any program that uses any of the GEM AES before the Desktop program is started, which does not happen until all of the auto folder programs are executed.

This is because in order to fit GEM into the ROMs, the clever guys at Atari replaced a lot of the in-line subroutine jumps and some other code with line-F "opcodes". The line-F trap vector is not set up to the GEM line-F handler until the desktop program is started, and some of the handling appears to be in RAM.

Also, GEM requires a lot of context, which must be initialized before it can be expected to act in a reasonable fashion. This is also done when the desktop is started.

Even programs that use Line-A graphics must be careful when running from the auto folder -- They must provide their own line-a structure since there is none set up yet by GEM. This is not much of a problem, though.

The solution is to use a program that somehow forces the desktop to
execute a program after it has started. I think this is usually done
using a desk accessory. I think such programs have been posted to
the net or are available on CI$, and other pay-services.

I hope this helps clear things up.

A UN*X style "strings" utility for the ST, check it out.

1139. Re: questions Re: Hard drives for the ST

Newsgroup: comp.sys.atari.st
Date: 1988-01-12 16:17:53 UTC
From: roydant@hpgrla.HP.COM
Message-ID: <4110004@hpgrla.HP.COM>
Source record: 255139

After reading the initial note I dug out the schematic on my 1040 st
and looked at the driver circuit for the DMA port and confirmed that the 18
inch limit was put on by Atari because of the lack of proper drivers and
termination resistors. (I assume for cost reasons)

So in a normal production run of computers and peripherals the margins
dictate the maximum cable length of 18 inches. This does not mean that you
can't run longer cables for a specfic machine, but the chance (no I don't
know the sensitivity) of data dropout and harddisk retries is increased.

With some rework on the inside of your st (i.e. void warranty) and the
proper modification at the ACSI to SCSI for proper drivers and terminations.

Roydan Tomlinson

Well... that's not true. We *never* planned to use the Ricoh engine, which I
I believe runs at 6 pages per minute. Nor do we use the Canon engine now.
The actual engine being used is the TEC, which is 8 pages per minute, writes
white (which gives nice solid blacks), and which should be cheaper to
operate.

Let me describe this morning. I am using a Sun 3/50. From this 3/50
I am rlogged into two sun servers, an alliant, and a gould 9080 (all
unix 3.x), on one of the servers. I was runing Gnu emacs reading my
mail and recieved a request to 'talk'(electronic talk) to a user. I
threw gnu into the background, and ran talk; the user told me that TeX
wasn't processing a file properly. I thew talk into the background;
grabbed the file and ran TeX on it in the background. While waiting
for it to TeX I resumed talking to the individual asking assorted
questions. When TeX was done I put talk in the background again and
read the log file and saw no error so I ran dvi2ps on it in the backgound
and found out when I started talking with the user again that
he actully was talking about dvi2ps not TeX. So I stopped talk again,
read the output from dvi2ps and found that a font was missing at the proper
mag step. I told the user to wait about 15 minutes and everything
would be fine. I then ran metafont then gftopk then cp all in the
background while I resumed reading my mail.

Now I don't know about you, but I would hate to have to do this with
some little os that doesn't do multi-tasking easily. The above
sequence took about 5 minutes of my time; if I did not have
multi-tasking it would have taken at least 1/2 hour.Ok I guess that
you could call this "power use" but I assume that people don't want
toy computers, right? Please saying that multi-tasking is not needed
is sort of like saying you don't need hard-drives; sure you can do just
about everthing that you want but would you even want to?

I just recently got a copy of the new game from FTL (the makers of Sundog) for the Atari ST. It is called Dungeon Master, and is truly amazing. It's a Wizardry type of game, where you enter a dungeon with your band of feckless heroes and attempt to get to the bottom and back up again with a treasure of some sort. The view is from the first person perspective. The graphics on screen are truly amazing. They are astoundingly beautiful. There are objects that you must search for on some of the walls, and find, and use yourself if you want to get very far in the game. Gameplay is quite good, as well.
But I didn't get on the net here to give all you illustrious people a review of a game. What really amazed me about it was that in the newsletter that came with the game, FTL themselves say that there is more than one Megabyte of graphics in the game. I can deal with that. The amazing thing is that they fit all of this on one single-sided ST disk. And they also managed to get the program on there, too. This has got to be one of the most impressive feats of compression I've ever heard of. If anyone has any idea as to how they did this, I'd really like to hear it. It sorta makes you wonder just what they could fit on two double-sided disks.
In any event, if you have a chance to play-test this game, go for it. It's truly an amazing feat of programming. Oh, and does anyone know what System Error 60 in the game means?

Over the holidays, I sorted the stuff I took off the net over the last six months. In the Professional GEM series, I found I had a uuencoded file called source2.uue but no source1.uue. Could some kind soul send me the first half of the uuencoded set? If an ARPANET site has it online, I could anonymously FTP the file.

Thanks,

Craig

1146. ST Writer Questions

Newsgroup: comp.sys.atari.st

From: AB084@DK0RRZK0.BITNET
Message-ID: <8801130043.AA03818@ucbvax.Berkeley.EDU>
Source record: 255146

Yesterday I received ST Writer. I like the program, it seems rather usable.
I have two questions and would be grateful for answers.

1. The manual says that "a program and instructions to let you customize
this file (i.e. the printer configuration file) will soon be available
for downloading from the Atari BBS". *ARE* they available. If so, could
someone send me a copy?

2. Is it possible to modify the default values in the Print Formatting Block,
such that the modified values are inserted whenever a new file is created?
(DIN paper format is different...)

Thanks a lot

>I have found most of the bugs. Of course, if there are bugs there
>then it is awfully difficult to get formatted documents for your
>printer 8{). However, there are bugs in WP.prg as well.

I will say that the printer configurations that are supplied on the disk are not quite correct, at least for the Panasonic. (seeing that this is the only printer I tested, as I have a KX-P1090 (plain jane))

What I had to do was to set the end of document to a full reset instead of what they provided, seing that they set the configuration at the start of each document, this causes no problems. This I really *never considered to be a bug (being that it was a preset configuration) and was a minor change only. After that, the document went out to the printer perfectly just as the TEST file was supposed to.

As far as the two versions, that could be entirely possible. As I stated, with the version that I have No problems for at all. My main problem with the many problems described by many users of the program, were really due to the lack of reading a manual, which would have cured there preoblems, is they would only read HARD paper copy.

My configuration just for edification is

1) 520ST -- bumped to 1 meg
1) MonoChrome monitor
1) Color monitor
2) SS/DD drives
1) Kx-p1090 printer

I do run a ramdisk with the program (drive D:) at about 200K. Other than this we seem to be running pretty close systems.

1148. (beta) Gulam keyboards

Newsgroup: comp.sys.atari.st
Date: 1988-01-13 11:33:45 UTC
From: ralph@lasso.UUCP
Message-ID: <8801131133.AA04602@lasso.laas.fr>
Source record: 255148

Well folks, I just received the GULAM.PRG program, binaries only, from the kind soul cc'ed above. It looks great but does seem to require an American keyboard -- at first glance. I was just looking around some old Info-Atari16 Digests hanging around -- as well as at GULAM's binary code on Unix GNU emacs, in order to find the keytables. As mentioned, I do not have the Gulam documentation. I have a French keyboard!!

I was expecting to have to edit Gulam's keytables, etc. in order to use it on my 1040 ST. WELL, to my surprise the answer is NO!!!! I don not know if Axel Mahler has modified the Gulam that he sent me or not. (Please confirm, Axel.) In my version of Gulam.prg the "help" key is bound to a simple help description of gulam. Well, if I enter shift-"help" two things happen:

1) The "help" description is disabled from the "help" key.

2) My French AZERTY keyboard is completely recognized by Gulam, for all the std. ascii characters. The French accents, which I believe are over 7F hex, remain unbound.

If I now type "help" on the keyboard, that reactivates the "help" key binding and reestablishs the American keyboard description.

Has anybody else recognized this functionality of Gulam? No editing of GULAM.PRG was necessary. Great, isn't it!!!!!

1149. Spinning floppy problem

Newsgroup: comp.sys.atari.st
Date: 1988-01-13 11:51:39 UTC
From: ralph@lasso.UUCP
Message-ID: <8801131151.AA04609@lasso.laas.fr>
Source record: 255149

Awhile back in Info-Atari16 Digest v. 87, n. 392 Warner Young (formerly c9c-eh@dorothy.Berkeley.EDU) described his problem of having his floppy keep spinning when he boots his hard disk.

I recently have found out that I have the same problem! I have a 1040 ST with an SH204 hard drive. At cold boot or warm boot, the floppy motor starts spinning immediately! Then the floppy light comes on when the ST checks to see if a floppy is there! The light goes off and the ST continues by booting from the hard disk (I use AHDI.PRG), but the floppy motor keeps spinning.

Does anybody else have the same problem, or has found a solution? I have only recognized the problem when turning off my hard disk at night to work quietly -- with it on, one doesn't hear the floppy motor at all! I have a kludge whereby I access the floppy from desktop (with a floppy in the drive) and that turns off the continually spinning motor. Why doesn't the boot turn off the motor? Is there a signal getting lost? Any help would be appreciated.

While I'm on the subject of booting, are there any differences between the hard disk boot programs that float around on the net? I have AHDI.PRG. I've seen posted HDB_V2.3. Is it for another drive?

When a hard disk is installed, will an ST boot off of the floppy *only* if it has a boot sector? If so, how does one put a boot sector on a floppy? I have not managed, w/o kludges, to boot a floppy while having my hard disk on.

Thanks for any comments and help.

Subject: Fast life program for Atari ST (and other 68000 machines)
To: info-atari16@score.stanford.edu

Here is a fast (400,000 cell-generations/s) life program for monochrome
Atari-ST computers (which should port easily to other 68000 machines).

It animates all 240,000 pixels on the screen. Feel free to add a
better user-interface!
```

[that means about 2 full screen updates per second, right ? Not a record
by any means - let me tell you about the CAM I saw doing full screen life
at full video rates (60 (or at least 30) full screens/second). --BillW]

But how does it go so fast? It sums the neighbours of 32 cells in one
pass, by synthesizing addition instructions out of logical operators.

The rest of this file is a shar containing
life.c - mainline
gen.s - quickly compute next generation
life.uue - uuencoded life.prg (Atari ST only)

Have fun!

Jan Gray jsgray@watrose University of Waterloo (519) 885-1211 x3870

Not quite right. ST World and ST Informer are published by different
companies. They seem to be rivals.

Sorry. The blitter ROMs do not have any changes to the 40-folder limit.
The next ROM rev should take care of this, but it won't be done for a while.
The article must have been written before the ROMs were frozen.

Will do, but I have logged in to several STadel boards and still haven't
changed my opinion. Maybe the reason you find them more friendly now is
that you've had 6 months of experience!

> One other thought. Stadel is best used as a message base system. You
> can log on with minimal fuss, quickly find the section you are

> a lot faster than any other BBS that I have ever used.

OK, I'll buy that part. But you can't leave messages "TO" a specific person.

> If you could reserve say three of your systems for downloading

Based on the current usage, I'd have to set up 4 for downloading and 1 for
messaging. But, I am philosophically opposed to that -- I think it would

reduce message traffic. Some people call mainly to download but also read the messages. And messages are my primary reason for having the board.

Hmmm... maybe I should go with STadel... it would cut down the downloaders :-)

From: engst@tcgould.tn.cornell.edu (Adam C. Engst)
Subject: VCR -> Atari color monitor
To: info-atari16@score.stanford.edu

Having taken a fair amount of flak from several people who seem to think me stupid because some site truncated my messaged, I will ignore them and ask again. Does anyone know of a cable or interface box which allows one to use an Atari ST color monitor (SM 1224) to display VCR tapes, movies etc? It seems that there should be such a beast, and Allan Pratt agreed with me, but neither of us has yet found one. Essentially, it would have to allow composite output to be displayed on an RGB screen, something which should be possible. This would allow you to have a VCR, which has a tuner and all that sort of TV stuff built in, with your computer monitor, which lacks all the TV stuff but can show a decent picture. Please send all information to me and I will summarize to the net.

Thanks - Adam

From: mtune!lzaz!hcj@rutgers.edu (HC Johnson)
Subject: SH204 disk errors
To: info-atari16@score.stanford.edu

There have been many posting with regard to strange ST behavior
when using the SH204 disk.
After discussing this with Chris at BMS I learned the following:
1. SH204 seems to report 8 drives per controller. I saw this with
the BMS driver on my SH204. Also Magic -Sac describes this.
2. That isn't the problem.
3. SH204 CANNOT report ANY ERROR to the computer.

So why doesn't everyone die on a disk error? The Adaptec interface
does the retries, and if successful, all is well. What happens
if the sector is BAD? You read in junk, fail to get the error message,
and see strange things.

BTW, hdx CANNOT mark as bad the blocks in the root directory or the SAMS.
This creates really strange problems when a block changes, as when
adding files and suddenly 5 megabytes dissapper.

I solved my problems 2 ways.
1. I changed hdx to accept a list of bad blocks and let Adaptec remove
them permanently.
2. I now use a BMS controller. Highly recommended.

Any one want to buy a slightly used SH204?

Subject: UniTerm available for FTP
To: info-atari16@score.stanford.edu

I have made UniTerm v2.0a (currently 006) available for anonymous FTP
on our host cs.orst.edu. This machine is on the NSFNET, which means
that it's not unusual for it to be unreachable on occasion. As usual,
please limit access to after working hours.

The files are in the directory pub/atari/uniterm, and you should
probably get "README" first to see exactly which files you want.

And if you like UniTerm, you should send Simon a check. I hear he's
saving up for an Amiga (I know I'll regret joking about that -- more
likely he's saving for a color monitor)....

(and many other contributions)

I think that there is an aspect of this argument which seems to have escaped many contributors: a good multitasking operating system gives the user *far more* than merely the ability to launch more than one application at a time.

Principally, the application designer is able to design multitasking applications which use daemons for part of their functioning, but appear to the user as single programs, just cleverer. We all use these facilities in Un*x without thinking about it (cf. elm), but for the software designer the benefits are cleaner design of complex programs, and for the user a nicer, cleverer application (spool printing, concurrent messaging, simultaneous computation and display in complex graphics applications, etc etc).

The bottom line here is that the *average user*, if there is such a person, does not have to bother to understand, or even know he is using, a multitasking opsys to benefit from it.

Hi all, well it is time to clean out the old software liab. I have decided to seel the following items due to lack of use on my part, this does not mean that they are not good, it just means that I am not using them and being a univ. student every dollar counts.
The following are for sale:
1. Alice Pascal-also includes 1 free update card(nice Pascal, lots of help)
2. GST-C, updated version 1.3 from Antic software, used to write 1ST WORD
3. GFA-Basic and GFA Book, Also have lots of source code to go with this one.

I may have the GFA sold, but until there is money in hand it is for sale.
Prices are based on CDN Dollars.
Item NEW USED
Alice $119 $70
GST-C $109 $50
GFA+BOOK $140 $90 (these packages are almost brand new)

If you are interested in any of these packages, you can get me at the following numbers:
School 1-(902)-542-2312
Home 1-(902)-466-5345

later
Barry

P.S. Will trade any of the above for anything of equal value!

1153. tos roms and blitter

Newsgroup: comp.sys.atari.st
Date: 1988-01-13 17:44:00 UTC

Message-ID: <8801131858.AA25909@ucbvax.Berkeley.EDU>
Source record: 255053

I have been hearing contradictory things. First I hear that the new TOS in ROM will be available to ST developer's. Then I hear that they won't be available for the 520 and 1040 ST. I also hear that Atari will swap the TOS and MMU and add blitter on any ST for around $100, if you send your st to the atari headquarters.

What is the real story, Neil ?

1154. Re: Multiuser BBS & HDSCAN/DISKTOP

I was watching a PBS show on TV the other night, something called The Computer Chronicles. They were talking about manufacturing in Taiwan, which was pretty interesting, but then the phone rang. I started recording the show on the VCR and answered the phone. When I finished on the phone and went back to watch the parts of the show I missed, I was pleasantly surprised. They were talking about Atari! All of a sudden, this voice starts speaking, the picture flashes on the screen, and lo and behold, Neil Harris is really a normal looking person, not some forked-tongue demon who delights in feeding Atari users vicious rumors. Course then the tape ran out after Neil had said only a few words :-).

I just thought the net would like to know that Neil actually was a real person, since sometimes he isn't treated as one.

Thanks a lot for the help with finding me a dealer in my area, Neil!!!

1155. The beginning of the end of the disk drive problems

Newsgroup: comp.sys.atari.st
Date: 1988-01-13 19:03:37 UTC
From: engst@batcomputer.tn.cornell.edu
Message-ID: <3368@batcomputer.tn.cornell.edu>
Source record: 255055

I finally got my Fujitsu 3.5" floppy drive the other day and hooked it up. It seems to be completely standard, both in size, mounting holes, and sensing the write-protect line. In other words, my ST works again! I'm going to put the Fujitsu in the case with the hard disk system when I get it to avoid cutting my case open to make room for the Fujitsu's button. Then I can leave a boot disk in the old drive and use it only to boot from.
I talked to BMS about their boards, and the guy said that their standard controller doesn't deal with RLL encoding (which increases storage by 50%), but they do sell another controller which does for an extra $50. They also have some cases/power supplies which are big, but work fine with their setup (ie enough room for two drives and the cards). Their cases also cost $50, which actually is cheaper than any other case/PS combo for a hard disk than anything I found in the Computer Shopper. Alas there are no good electronics stores in Ithaca. So for a floppy/hard drive combo the prices would be:

BMS board set with RLL $300
Seagate ST238 30 meg drive $250
Fujitsu 3.5" floppy $120
Cable from floppy to drive port $30
Case and power supply $50

$750

That's $150 cheaper than Astra's system and this one has a 30 meg hard disk instead of 20 meg. Not too bad.

By the way, two companies make floppy cables, IB Systems and E. Arthur Brown. Does anyone have any experience for or against either company? Both seem to have interesting products, particularly E. Arthur Brown, but no one has ever mentioned anything about them.

The IFF stuff that we sell for $20 is and always has been a spiral
bound printed manual + a disk. The disk also contains the manual text
in addition to source/object/executables so that the disk can be useful
freely redistributed by itself by people like Fred Fish.

[]

Here is a warning to all ye hackers out there:

I tried the Supra hard disk driver SW on my Atari SH204 as it came
formatted from the factory. IT WORKED FINE. Then I got brave and
installed the Supra hard disk boot. DRIVE C DIED. I could not
fix it, even by zeroing C:, even with SUPEDIT.PRG. This may or may
not have anything to do with the fact that I used to have HDB2.3
hard disk boot installed. (I disabled that before installing the
Supra HD boot, but the HD sector editor in SUPEDIT showed sector 0
to have both "AHDI.PRGhahn" and "SUPBOOT.SYS" in there...)
Anyway, it's all my fault, of course.

So I had to reformat the drive. Surprisingly, both the Atari and the
Supra SW refused to format just partition C:, without clobbering D:
and E: --- is there a way to do that? (It works fine now.)

I could have fixed the C partition if I knew what is supposed to be
where on it. The C: partition boot sector seemed messed up (using
SUPEDIT) but filling up the fields with the parameters I saw in
the D: and E: partitions did not fix it. Any source of information
out there about HD boot/FAT/directory info?

Just for the record, here is what SUPEDIT claims is in my boot sectors now
(with the standard 4-6-10 meg partitioning): (all numbers in HEXADECIMAL)

branch: 4
filler: ><~aNu (that 'a' is an alpha)
serial: 244865
BPS: 200
SPC: 2
RES: 1
NFATS: 20
NDIRS: 100
NSECTS: 2290, 3000, 5000 for partitions C, D, E
media: 73
SPF: 12, 19, 29 for partitions C, D, E
SPT: 2E70
NSIDES: 2C73
NHID: 2076
evenout: 2F7C, 1B0C, EB0C for partitions C, D, E
checksum: 0

- Moshe Braner

PS: still in need of the patch that enables reading the hard disk
GEM partitions from MS-DOS under PC-Ditto.

Sure, I would not mind seeing it. But, I have indeed used STadel boards
more recently, and I personally have very little trouble navigating through
them. But they still strike me as counter intuitive, especially if you want
to download something. And I can't accept that in the boards I'm running.

The real story is, we'll be making blitters (in the same 64-pin package as
the 68000 chip) and the TOS ROMs (in the 6-chip set) available RSN to
existing 520 and 1040 owners.

Made my day, Adam. Thanks.

I thought the show did a really good job on the Taiwan manufacturing issue.
Which is good, because they filmed here for an entire day!

Did anyone see their coverage of Comdex? I haven't seen that one yet
myself, but I hear that Abaq got on at some length.

I've finished a port of NetHack to the ST. It seems to work reasonably
well (i.e. it only crashes once in every three games:-), so I was thinking
of distributing it.
However, it is not the most recent version of NetHack, but the previous
one.

So, I have a couple of questions:
- Are people interested? I'll post an ARCed binary to comp.sys.atari.binaries
if there is enough interest.
- Is there someone acting as a clearinghouse for NetHack? I.e. could I send
my fixes somewhere to have them incorporated in the next official
NetHack release?

Please answer by mail, not news.

From decvax!virgin!zinn!mem@ucbvax.Berkeley.EDU (Mark E. Mallett):
>In article <920@atari.UUCP>, neil@atari.UUCP (Neil Harris) writes:
>> What good does it do to start rumors like this?
>> Most ridiculous rumors of 1987 awards:
>Here are some more:
>3. .. something called a MEGA 2 and a MEGA 4.

A person here bought a Mega 4 and I got a brief look at it, so it appears that one does indeed exist. The story of what he went through to get it was truly incredible...seems it is easier to find the Holy Grail or Noah's Ark than to buy a Mega 4. Maybe Atari is trying the Rolls-Royce marketing strategy: make a few of them, and let everyone fight over them and pay high prices for the privilege of owning a limited edition.

One interesting point...he said he found a lot of places that wanted to sell him a Mega 2. Has anybody figured out how to upgrade a Mega 2 to a Mega 4? For what the guy here payed for the Mega 4 (all things considered) it would have been cheaper to get a Mega 2 and upgrade it. [In fact it would be MUCH cheaper to get a 520 and upgrade it to 4 megs...but that wouldn't be quite the same thing...]

What's it take to upgrade a Mega 2?

1172. Lattice C 3.04 is buggy.

Newsgroup: comp.sys.atari.st
Date: 1988-01-15 14:09:00 UTC
From: NETWORK@FRSAC11.BITNET
Message-ID: <8801151316.AA16209@ucbvax.Berkeley.EDU>
Source record: 255072

Date: 15 January 1988, 13:14:47 GMT
From: NETWORK at FRSAC11
To: INFO-ATARI16 at SCORE

Lately I had to to "make" a quite large program, including assembler
and C sources, with the MCC Lattice C 3.04.01 development tools.

1. Make seems to send real fantasy arguments to programs exec'ed from it.
(Make does not call a shell, it exec directly the lines...)
2. Link is so picky that it barely works under make...
(-nolist bombs the whole thing ... amazing)
3. Link does NOT handle properly the mix assembly/output and C/output.
(assemble is with MCC Macro assembler, C is with Lattice, all in
GST format) There is a problem with the XDEF & XREF in assembly
binaries, only in the "mind" of link...
4. I had to Compile with DRI format output, assemble with AS68,
and link with link68... still slow, but it is working flawlessly.
(quite a proof that the GST linker is buggy...)
5. MCC Lattice C is totally lacking the signal() thing, I need it.
What can I do ???
6. In C, always with Lattice C, getenv/putenv are not really working,
I can not get anything correct from envp or environ after a putenv...
Any solution ?
7. The forkv??() function family is not working, I had to write my own.
8. System() does not seems to work, in the manual they talk about a
COMSPEC environment variable, this is highly non standard, whatever it
is... Does anybody knows what is it ?
I use system() in MWC, and it is working very nicely under msh,
what the h... is doing msh to have it work ? (shell_p, COMSPEC,
SHELL ... ???)

Please if you know anything that can help, just make me a mail,
I may come up with a product interesting to you, and free.

Thank you for listening.

Subject: $$$FREE$$$ multitasking kernal!

The comments made by David Beckmeyer are _exactly_ the type
I've been waiting for. I would love to have a low-cost
multitasking kernal available for the ST!

Sheesh, it doesn't even have to be free. I'm sure most people
would be willing to fork() out a few bucks for a really nice
multitasking kernal. However, if it's really going to make
a dent, it's probably going to have to be PD or shareware.

PLEASE PLEASE PLEASE come out with such a system!

(Hell, something this good is almost enough to give a man
religion! :)

>copy they know works?

There must be some timing-dependent feature in the way in which this
program simulates a mono reboot and startup. I have tried it repeatedly
on one machine, finding that the only way to get it to work was to
power down and then run the program. Reminds me of the "synch" funnies
with Spectrum 512.

Alternatively, perhaps there are lomem variables which must be reset
for this thing to work reliably; power-down accomplishes that.

1175. Re: Spinning disk HD boot

Newsgroup: comp.sys.atari.st
Date: 1988-01-16 01:34:18 UTC
From: bryan@ihnet.ATT.COM
Message-ID: <593@ihnet.ATT.COM>
Source record: 255075

When you use AHDI to boot off of a hard disk you should have a floppy disk in drive A. The ST will not boot off of this disk unless it has a boot sector on it. With a formated disk in drive A the ST will boot Very quickly from the hard disk. I usually keep a copy of "SHIP.PRG" on drive A, which I usually run before I turn off the HD. Note be sure there are no open windows to the Hard Disk when you run SHIP.PRG. As for why the light stays on, I can only guess it has to do with the fact the ST is trying to read drive A when no disk is in drive A, and therefore is getting some sort of read/drive error.

Unlike MS-DOS system The ST looks for a BOOT sector first at the Cartridge Port then on Drive A, Drive B then it looks for a Boot sector on DMA Logical Unit 1 (The Hard Disk), If it finds a boot sector on drive A it boots drive A and If It Does not Find a boot Sector on Drive A it looks else where until it finds a Boot Sector. When you Instal AHDI you are actually installing a Boot Sector on the Hard disk.

Around here, it's pretty easy to find a Mega at a dealer. They seem to be
prety abundant. I have a few friends that have both varieties. One store
I know stopped carrying the Mega line because the store wasn't selling any
of them.

From what I've seen, it's not too tough to upgrade a Mega 2 to four megs of
RAM. You'll need 16 1 mbit DRAMs, 16 capacitors, and quite a bit of
whatever you use to desolder things. After removing the solder from the
holes where the chips should go, all one does is stick the chips in and add
the capacitors, solder it all up and off you go.

The price difference (that I've seen) seems to make buying a Mega 4 about
$200 cheaper than buying a Mega 2 and upgrading it.

Oh well.

[a line for the line eater]
I was skimming through a recent (this week's?) Infoworld and happened upon some interesting rumors in the "Robert X. Cringely" rumor column in the back. Since I was just skimming, I didn't get all the details (so if you read the article or have any other info, please comment to the net!), but here goes:

According to the little blurb, Atari is working with Next, Inc. on creating a 68020 machine that could run Mac & ST software. Next, if I read it correctly, is the company Steven Jobs formed after he left Apple. Apparently he has developed some Mac emulation hardware but needs someone to make it cheaply for him. Apparently a deal is being worked out where Atari will get Mac technology in a trade for Atari's Amy sound chip (to be used in a future Next workstation). Atari, I'd like to hear from you about this (even a 'No comment' !).

Source record: 255078

[a line for the line eater]

Well, as I'm getting busier and busier, I find that I'm almost never using some of my software (especially most of the games). Because of this, and also because I could use the money for some hardware purchases, I'm going to sell off a bunch of my stuff. Many of these programs have been used very little (some only booted a few times), and all come with the original disks, docs, and packaging.

A Mind Forever Voyaging -- $22
Balance of Power -- $27
Black Cauldron -- $20
Brattacus -- $17
Chessmaster 2000 -- $27
Expert Opinion -- $35
Harrier Strike Mission -- $16 (color only)
Lattice C, ver 3.03.02 -- $50
MCC Macro Assembler -- $32
Ogre -- $15
Phantasie -- $21 (color only)
Rogue -- $17 (color only)
Silent Service -- $20 (color only)
Star Fleet I -- $25
Star Glider -- $22

also, for the IBM, Star Flight (with 5 1/4" & 3 1/2" disks) -- $27

I'd also be interested in trading for other software, including CAD 3D 2.0 & associated programs & libraries, Spectrum 512, and Word Perfect (of course, one of those programs would be worth more than one of mind, plus maybe some money in balance). I'm willing to discuss any of these prices, of course. I can be reached at the places listed below. Thanks!

1180. In defense of the Amiga/Atari ST flame war

Newsgroup: comp.sys.atari.st
Date: 1988-01-16 05:57:41 UTC
From: karl@sugar.UUCP
Message-ID: <1401@sugar.UUCP>
Source record: 255080
Cross-posted to: comp.sys.amiga,comp.sys.atari.st

There has been an ongoing "net war" between a handful of vocal Atari ST and Amiga people. It heats up once in a while, with a flurry of virulent postings, then cools down, then heats up again. After it's heated up, a handful of people post about what a waste of time and/or net resources it is. I'd like to speak for a moment in defense of the "war."

First of all, concern about the wasting of net bandwidth are overblown. "You're wasting net bandwidth" is the bogeyman on usenet, isn't it? I speculate that most of the people on the net, including those who post messages like that pay nothing for net access. (No tons o' followups from the exceptions, please) I'd estimate the ST/Amiga war consumes no more than 50k/month, trivial when compared to total traffic on comp.*.amiga and comp.*.atari.st and supertrivial when compared to total net traffic.

Second of all, it's not really hurting anybody, at least not much. The people who could conceivably claim they've been harmed by the war fall into three categories: those who've had their feelings hurt because their computers were criticized, those who've had their feelings hurt because they were flamed and those who would rather not see the material. The first group need to get tough. Flame victims have some legitimate grievance. Usenet postings are all too often personally insulting, but that's hardly the exclusive province of the Amiga and ST groups. As for the inconvenience caused for those who don't want to read the stuff, well, it's really not all that much. ('though you'd never know it from some of the followups.) I mean, hit 'N' if you don't want to read it. ("vn" users have an even easier time of it.)

Third of all, and in refutation of the second most common complaint about the war, something good can come of it. For example, David Beckemeyer is seriously considering placing his Atari ST multitasking C shell in the public domain, partially as a result of the Amiga/ST flame wars.

And finally, it's entertaining. Yes, I have to admit that I actually enjoy reading the flames. I like watching the ST guys get flayed :-) :-) :-) It breaks up the monotony of all of the useful and informative Amiga messages from the likes of Chuck, Fred, Bryce, Leo, George, Carolyn, Andy, Peter et al... can't speak for the ST camp, but hey.

Subject: WordPerfects???

I've been considering WordPerfect, and I'm getting a little confused. It's as
if there are two different WordPerfects. On the one hand, Pavneet Arora writes
from Canada and says:

>In response to Neil Harris' comment that the support is excellent, I have
>a few comments of my own:
>
> 1. No company, software or otherwise, should be able to release
> a product that doesn't even come close to working.
> Bugs are one thing - fatal bugs another. I use the following
> analogy - If I approached WP and asked them to give me
> a copy of the software, and then told them that I would pay
> them in a few months i.e. whenever I could afford it, I would
> not expect them to hand over the package. And yet, WP has
> taken money from users and then handed over a useless package
> without ever notifying any of its users that there are problems.
> And when a user tracks down the bugs and calls WP, they say
> they are aware of it and a working version should be out soon.
> Soon in my case has meant 3 months now, and I still don't have
> a working version.

..etc.

>I think the larger issue here is the ethics with which high tech companies
>operate. Personally, I don't feel that WP has thus far exhibited anything
>that
>qualifies it for the praise that Neil Harris had to offer. My experience
>has been in dealing with WP both in Canada and the US for the past three
>months now.

On the other hand, Rich Dankert replied with glowing praise to a request for
information on WordPerfect:

>In article <2143@cup.portal.com> RJknees@cup.portal.com writes:
>>Hey everyone! I'm looking for someone who has (or has used) WordPefect on
>>the Atari-ST. I'm thinking of buying this software!
>

..answers to questions 1-4

>>
>>5. Any other opinions or comments RE: Wordproccesing on the ATARI-ST
>>
> Contrary to all the comments from user's of Word Perfect in the
> negative aspect, I can say that the version I got didn't have all the
> bugs that I had seen mentioned. In fact Word Perfect Corp. is
> one of the best software makers that I know of. If you OWN the

> program, and have a problem with it, and they have a newer version
> of it, they will send it to you, second day air sometimes.
>
> This is one software maker that really backs their product!

What's the deal here? Are we talking about two different versions of WordPerfect for the ST here, is there a different version in Canada, or does Pavneet Arora use features that Rich Dankert doesn't? ? Can someone clarify? Also, some discussion of other peoples experiences would be great.

And, yes, Virginia, there is such a thing as multi-tasking ;-).

Cheers--

Subject: Atari ham radio net info
Date: Fri, 08 Jan 88 14:34:21 EST
From: jhs@mitre-bedford.ARPA

This may be old news to many readers, but I just learned about the Atari Microcomputer Users' Net, a ham radio discussion group focused on using Atari computers, especially in ham radio applications (but not exclusively). The net meets Sundays at 1600 Zulu (GMT) on 14.325 MHz. (1600 Zulu is currently 11 AM Eastern time, noon during the summer.) David Byrd, KD7VA, is the Net Control Station. Dave is the creator of a well-known 256K plus upgrade for the 800. Gil, VE4AG, publisher of Ad Astra, is usually also on frequency. The group maintains an extensive disk library, emphasizing but not limited to, ham radio applications. Both ST and 8-bit software and hardware interests are covered by the group.

Readers who are not hams would need to find a local ham to participate actively in the net, but they might anyway enjoy listening in on a shortwave receiver tuned to 14.325 MHz on Sunday mornings.

IFF stands for "Interchange File Format". It is a stanard for creating file standards. The intent is easy transfer between machines and programs. Very nice.

There are IFF definitions for Musical Scores, sampled sound, digitized pictures, etc.

You can purchase the entire "IFF manual" for $20 from:

Subject: What's DVI?
To: info-atari16@score.stanford.edu

Yesterday I FTPed and downloaded UniTerm v2.0a (thanks, whats-yer-name at
Oregon State) to find, to my chagrin, that the documentation is in DVI format.
Well.. what's DVI? How do I get this file full of gibberish to make some
sense? Be warned that I have no printer..

Subject: Re: Need info on 2400 baud modem and C
To: info-atari16@score.stanford.edu

I recently bought a SUPRA 2400 baud modem. It seems to work just fine.
I cannot comment on reliability, because of my limited experience with
it. I can say however that 2400 baud makes working remotely possible, where
1200 did not. It is possible to do full-screen editing and remain sane.

There are a number of possible reasons that the SUPRA modem is inexpensive.
It is not in a fancy box, there aren't lots of pretty lights and nobs.
It does not, at least the package I bought, come with communication
software.

Subject: MULTI-TAXING

THE oddball discussions on multi-tasking have made me wonder why
no one has thought of the obvious use-- figguring out your taxes. I
don't know if the US system is as silly as Canada's, but what has
always bugged me here is that you have to fill out innumerable
different schedules and calculate them depending on where your money
is coming from, because different sources of income are taxed
or treated differentlty. So you run your tax program. All is well
until it asks you to fill out sked 4, capital gains from real estate.
So you stop and start filling in what property you bought, how much
of it you sold, what proportion of the gain is taxable, etc. And you
go back and fill in one figure. Then it asks you about dividend
income from domestic corporations (taxed at one rate) and from
foreign corporations (taxed at another) and you stop to figure that
one out. Then it asks you to fill in your income from the oustide
consultancy work you've done that year, (minus expenses allowable)

and so on and so on. Does no one see here what multi-tasking can do?
In the background you can have a batch of separate schedule programs
doing the dog work all at once and feeding the results into the
main tax program.
Software writers who haven't yet thought of this -- go ahead and
use my idea. Just remember to send me a copy of the program. Canadian
form, please.

Subject: Re: Multiuser BBS
To: info-atari16@score.stanford.edu

[Good morning, Mr. Line Eater...]

Neil,

With STadel, you may not be able to leave a public message directed
to a person, but if it's public, why not simply put the recipient's
name on the first line, and if need be, send them Email saying that
there is a public message in such-and-such a room. Also, those people
most likely to get public messages (such as yourself) could have a
room (message base) for that sole purpose. With STadel, you can have
64 "rooms" on a system. You could have 5 different boards with a number
of netted rooms as well as having a purpose to each separate board;
say, one for graphics, one for MIDI, etc. If you wanted to net with
Atari Canada, you could even net some rooms with them. Messages in
the rooms can be netted automatically or you can give the general public
netting privs.

I, personally, don't think STadel lacks in the up/download department
either, but it is "different". Rooms can be made directory rooms. You
can download a file right after you read comments about it if you want
without having to leave the message base or going into a "file" section.
You can send files from system to system through netting. You can make
directory rooms that are either upload or download only. The only thing
I find at all lacking is the description area. People tend not to describe
their files well.

As for new users on STadel, there are some tricks, but once people are
used to it, it is fast and easy, and best of all, NOT redundant! There
are help files and tutorials available. Most of the STadel users I know
(including myself) caught on very quickly. BBSers who are serious tend
to be fairly clever about such things. A simple explanation that the BBS
is like a large building where you wander from room to room reading new
messages and leaving messages usually helps, as does explaining that
everything you receive from the BBS is done with some kind of a Read,
and everything you give to the BBS is done with some kind of an Enter.

In case some of you hadn't figured out, yes, I run one of these beasties.
If you want some more information or would like a little tutorial about

using STadel (which also comes in Amiga and MS-DOS flavored Citadels, btw),
drop me a message. It may take a day or two to get back to you, but I will
indeed get back to you. There are a bunch of addresses where I can be
reached down below...

Neil, I have had trouble finding a path to you from Bitnet, I'm afraid,

1184. ANALOG - ST/Log bought out

Newsgroup: comp.sys.atari.st
Date: 1988-01-16 14:48:33 UTC
From: bruce@ektools.UUCP
Message-ID: <1010@ektools.UUCP>
Source record: 255084
Cross-posted to: comp.sys.atari.st,comp.sys.atari.8bit

This notice regarding ANALOG and ST/Log was posted on Delphi:

ANALOG is in the process of being bought out by a very large publishing company based in Los Angeles, California. The publishing company will provide printing, distribution and subscription services for ANALOG and ST/Log Magazines. For the most part, the editorial content will still be lead by Lee Pappas, Clayton Walnum and the assortment of contributing editors currently adding their prose to the magazine.

The first issue of ANALOG and ST/Log that will be published under the new company will be the March, '88 issues. These issues will be on the news-stands in late January, '88. After the re-introduction, ANALOG and ST/Log magazines will be published monthly with approximately the same coverage and substance as was previously made available.

Subscribers will continue to receive their issues as normal under this new arrangement. ANALOG will be installing an answering machine on their Worcester, Massachusetts phone number sometime this week. The machine will give more precise details regarding the publication dates and subscriber information.

1185. Another ARC (VAX/VMS) request

Simon Poole's DLII disk editing utility includes REORG.PRG, which will
reorganize files and directories on both hard drives and floppys.

>What's the deal here? Are we talking about two different versions of
>WordPerfect for the ST here, is there a different version in Canada, or
>does Pavneet Arora use features that Rich Dankert doesn't? ? Can someone

The truth, as usual, lies somewhere in between. The present incarnation
of WP does have a number of bugs, though few of them are really "fatal".
Most of them fall into the class of minor annoyances (such as the infamous
"key-click" problem). One of the most serious, to my mind, is that WP
doesn't clean up after itself properly when exiting -- at least the "Canadian
version" :-) doesn't, running on a mono 1040 with nite and moustrap resident.
It frequently bombs upon exit, and when it doesn't, will often lock up
subsequent applications (such as Uniterm). I just make sure I reboot every
time I exit WP -- no big deal, since it's not the sort of program you're
going to be using to dash off a quick note to the net.
Word Perfect Corp. should probably be chastised slightly for not
debugging the program a little more thoroughly. (They can make up for it,
in my books, by making the first upgrade free to current owners.) On the
other hand, even *with* its current defects WP is by far the best word
processor available for the ST at the moment; certainly it's very far from
being "useless", as Pavneet Arora suggests. I don't know about you, but I
don't think I could have waited much longer for a really decent word processor

for my ST.

1188. for Word Perfect users

Newsgroup: comp.sys.atari.st
Date: 1988-01-16 23:51:00 UTC
From: BRIGHT@DALAC.BITNET
Message-ID: <8801162357.AA18502@ucbvax.Berkeley.EDU>
Source record: 255088

Following is a small gift for Word Perfect users: an Icon program which converts .DOC files created by that miserable-excuse-for-a-word-processor-which-came-bundled-with-our-machines into WP files. To run it you'll need the ICONT translator and ICONX run-time programs (available at listserv@canada01, atarinet, and any number of other places, I imagine).
To translate the program, double-click on ICONT.TTP and enter 1STWD2WP.ICN on the command line. When the translator is finished, you can throw away the .U1 and .U2 files; 1STWD2WP.ICX is all you'll need.
To run the program, double-click on ICONX.TTP and enter 1STWD2WP.ICX on the command line (or "Install" ICONX.TTP with an ICX extension, and then double-click on 1STWD2WP.ICX itself). The program will prompt for the name of the input and output files (defaults to .DOC and .WP extensions, respectively). It will search the current directory and root directories of A: and D:, but you can specify a full pathname if you wish. (You could also edit the .ICN file before you translate it, if you want different default paths and extensions.) The program reads and converts each line of the input file, writing to output as it goes. Putting everything in a ramdisk will speed things up quite a bit. It will preserve all of the underlining, italics, bold, super- and subscripting in your .DOC file (but *not* 1st Word's light-faced type), and look after such things as hard and soft CR's. You'll have to fix up your block-indented quotes and whatnot a bit, but that's relatively easy to do once you've got the converted file into Word Perfect. Also, if you convert a .DOC file that was saved double-spaced, you'll get an extra space before each soft CR, so resave it single-spaced first.
This hasn't been tested much, since my main concern was to translate some of the papers I'd been working on into WP format. (This is the kind of "quick-and-dirty" application that Icon excels at, BTW.) The program worked fine for me, but use it at your own risk (and, it goes without saying, keep backups of your .DOC files until you're *certain* the .WP file is OK).

Now this is funny (as in odd, not laughable)! I've used the Atari boards and
the downloading struck me as far more counter intuitive than Stadel.
Which I have only used casually 3 or 4 times, and I have done up and down loads.

Well folks. Neil has made up his mind and the issue is now religion so
no amount of logic will move him.

21 00 22 00 23 00 24 00 25 00 26 00 27 00 28 00
FF FF 2A 00 2B 00 2C 00 2D 00 2E 00 2F 00 30 00

- i.e., looks distinctly like *** 16-bit *** entries.

Question: can somebody out there who knows about MS-DOS figure out the
corrections necessary so that MS-DOS (3.3) would read the partition right?
As-is it gets it all wrong except the root directory, so I suspect MS-DOS
reads the FAT as 12-bit entries.
Possibly: the media type is wrong, or it needs to be duplicated in the
first byte of the FAT?

Although 4 megs are great, they aren't too much good if half
(exaggeration) the software doesn't work. Mostly, I find it is games
that don't work, but it is a big pain, much of my old software is
now next to useless. For example

VIP
Mean 18
Rogue
Arkanoid
Championship Baseball
StarTrek
Swords of Kadash
ST Pool
Karate Kid II

I could go on, but I guess you see the point.

I was hoping someone had some easy, quick, dirty solution to these
problems. I did find a fix for StarTrek on Genie, but a friend got
it for me, and now I can't see if there are any more there.

Help!!

I have had some experience with the Beckmeyer MTC shell without the
VSH manager.
First comment: If you don't have a hard disk, don't even try it.

The package is heavily dependent on disk access, and trying to use a
normal floppy is just too slow.

Other then that, I have found the package to be very good. It
seems to be a very good emulation of the Unix system. This emulation
can be made even more complete with the purchase of a addition package
or two (MC-Tools, as I recall, is one of them.)

Some gripes I have is that they either have not made any revisions to the
package in the last year or so (which is very doubtful considering the
work that must have gone into the package) or that they just have not
sent out reports of these updates to their registered owners. (I sent in
my registration card about a week after I purchased the package but have
not heard from them since. On the same note, while they might have
updated the manual, the one that came with the version that I have is
really not that helpful if you don't already have a good background
in Unix.

Basically, though, I have found the package very useful and well written.

A friend of mine is looking for an integrated project management
package which will have actual resources used as input only once,
compared it with project projections, output reports etc.,
while also being tied into the payroll system.

Does something like this exist? If so could you please
send me the particulars. If not, then if anyone
could make suggestions as to how this problem may be solved, I'd
really appreciate it.

Many thanks in advance.

>doesn't clean up after itself properly when exiting -- at least the "Canadian
>version" :-) doesn't, running on a mono 1040 with nite and moustrap resident.
^^^^^^^^^^^^^^^^^

Just have a question here. Why the mousetrap program? The program
does allow the lockout of the menu bar, which may be the reason for the
not so clean break upon exit. Nite I can understand, to blank the screen
but another screen saver utl may solve the other problem your experiencing.

I must admit that I use WP from a cold boot, seeing that if i'm going
to be using it, I will be for some time,and when I exit the next program I
will most likly be using will be my terminal disk, though I do use the
terminal as a normal boot disk as it has my favorite .ACC's and ramdisk size.

Key click problem, well I can't say that I have encountered that
either, but then I don't have the volume up, as it slows my typing down ;^}.
Unless your talking about something different than I am interpreting.

I got my Mega4 without problems 3 months ago.
Currently I'm running a full implementation of Smalltalk80 on it.
(without blitter support sigh :-( )
>
>What's it take to upgrade a Mega 2?
Luck.
As my dealer told me, the Mega 2 has slow ram chips inside.
If you want to upgrade the Mega2 you have to replace these chips by faster
ones. Otherwise ram refresh might not work.

From: jrd@STONY-BROOK.SCRC.SYMBOLICS.COM
Message-ID: <19880118152255.0.JRD@GRACKLE.SCRC.Symbolics.COM>
Source record: 255099

I just stuck the .5 meg upgrade from E A Brown into my 520, bringing it up to 1 meg. Everything worked peachy, until I tried to recompile something with Mark Johnson C, at which point MJ's assembler wedged up totally. Everything else works marvelously; the ram's there, the ramtester loves it, I burned it in for an hour with no trouble, Uniterm loves it, other memory-hungry programs love it, etc, etc. The only ill effect is the MJC assembler wedging when I load it up.

Has anybody ever seen any effects like this? It seems pretty bizarre to me that making more memory available would cause a program to die like this, but that's what's happening. I tried several backup copies of the assembler, and the older version, but all do the same thing.

Any ideas will be much appreciated.

>> I can't think of *any* two tasks which I do on my home machine
>> which take enough time to make m/p profitable, and which could
>> co-exist sensibly with only two floppy drives.

I have one application I ran into at home on one of my single processing machines. I was dissassembling a rather large piece of code to find references to a particular set of routines. The disassembly output was many times as large as my available disk space put the references I needed were quite small. If I could have piped (UNIX terminology for sending the output of one process directly into the input of another process) this output into a grep (a line oriented regular expression pattern matcher) I would not have run into disk problems and would not have had to manually subdivide this work.

Clearly, since he doesn't have support for it he isn't doing some of the tasks he could be doing. Daemons for many purposes could be 'in the background'. Print spooling, disk capacity monitoring, memory consolidaters, memory allocation precalculators and well as piping.

Note: One of the fun things one can do with pipelines is send a chunk of text from inside a wordprocessor/editor through a formatting program as I have done with this message.

> What about formatting a floppy while you are running your Word-
> Processor, and your floppy is full? What I like is the ability in
> Multi-tasking systems, is the ability to SUSPEND, and not just
> ABORT a program, when I need to interrupt.

Actually, this doesn't take multiprocessing (i.e. concurrent running processes). To do it in the general case it does or one of the kludges like memory resident programs.

1203. Atari SH204 hardisk problems

Newsgroup: comp.sys.atari.st
Date: 1988-01-18 21:24:30 UTC
From: tainter@ihlpg.ATT.COM
Message-ID: <4655@ihlpg.ATT.COM>
Source record: 255003

I'm experiencing some odd behaviour with my ATARI SH204 hard disk.
Does anyone recognize these symptoms:

On what seem to be random disk accesses (reads AND writes) my
drive does what sounds like the initialization procedure it goes
through on power up and the disk operation fails. If I then
redo the disk operation immediately it has no problem.

Sometimes I will go for long intervals with no occurence other
times I'll take one of these hits every couple of minutes.

Also, when the disk gets moderately full (3/4) seeks can take as
long as 30 seconds and I think i've had some take considerably
longer though I never timed any longer than 30. Is this
reasonable behavior?

I am trying to get an idea of what the problem may be and if I can fix
it without having the unit repaired. To date I have not opened the unit
to check cable connections and chip seating. I have checked the external
cable and it is firmly connected.

Source record: 255005

I tried to use TURTLE to back up my Supra hard disk. Everything worked peachy until trying to write the seventh floppette, at which point it barfed, saying that it had encountered a fatal error writing the Ramdisk. I tried it twice more, and it barfed the same way on the same file every time. I punted the file, and it then picked a different file to barf on. I then wised up and did incremental backups, and it did about 7 more disks, and then got the same error. All the files that it was trying to copy were fine, no apparent corruption on the hard disk. It appears to be corrupting its ramdisks in some obscure way. Anybody seen this? Anybody got any ideas?

Next: I'm looking for source (68K code preferred) for floating point routines. Anybody got any handy? If it's any incentive, they're for the GNU C compiler, so if anybody wants to see it for STs, help me find the support code instead of writing it from scratch and getting it wrong a couple of times :-}

Finally, I'm still trying to get hold of Mark Johnson, of MJC fame. Either the various mailers are screwed up as usual, or he's dropped into a black hole somewhere. Mark, if you see this, please try to respond; I've got a bunch of bug reports and test cases for you!

From: euloth@dalcsug.UUCP
Message-ID: <281@dalcsug.UUCP>
Source record: 255006

I have just been playing with the VC.TTP, both the version which is

85791 bytes, and except for the W,and T commands works well.

86126 bytes, which has the T command working but not the W command.

The second one had the sources ARC'd with the program and a US Tax form.
There were mods made by Robert Bond, dating back to a year ago. Does
anyone know this gentleman?

I would like to ask if anyone has gotten the W command to work. I can't
seem to get it to print a file which can be viewed on the screen or printed
out. Is there a way to print to the printer?

Are the authors I listed above around on the net?

Message-ID: <1988Jan18.233950.29984@jarvis.csri.toronto.edu>
Source record: 255007

Can anyone point out a source of Ray Tracing programs written
in C? I would like to work on my own demos and do not have a lot of time
to figure out all of the mathematical transformations. I am particularly
interested in programs that allow the objects to move from frame to frame.

I have heard of a Ray Tracer by Tom Hudson, but I don't know if it
was ever released with the source code.

1208. Software (and other kinds of) copying

Newsgroup: comp.sys.atari.st
Date: 1988-01-19 06:13:15 UTC
From: david@ms.uky.edu
Message-ID: <8055@g.ms.uky.edu>
Source record: 255008
Cross-posted to: comp.sys.amiga,comp.sys.misc,comp.sys.ibm.pc,comp.sys.mac,comp.sys.atari.st,misc.legal

Pardon the wide distribution, but 1) this is one of those sweeping subjects that affects everyone, and 2) it doesn't cost the net anything extra to cross post. If you follow up, please make sure and include all the newsgroups in the follow-up ... I don't read most of the newsgroups listed above.

Anyway ... in comp.sys.amiga right now we've got this discussion going on about the evils of software piracy. It started (I think) in a discussion about a particular virus that's hit the Amiga world and propogates itself into the boot blocks of disks. But that's not important right now.

There have been a number of statements on both sides of the issue about copying software. It's easy to do and gives people free software; it's evil and raises software costs; keeps companies from investing efforts and money into a product; ad nauseum. I'm sure you've heard the arguments before.

But really ... what is the BEST solution? This problem exists in a greater context than just computer software. It exists in the music industry, movies, books, databases, and so forth. The point is that this technology we've been building has made it ridiculously easy to make duplicates of things. The technology has even become good enough that we can now make duplicates that are as good as the originals. And going further (beyond what I want to cover right now) we can even muck with our duplicate and add in new things or change what's there.

Such a context destroys the assumptions which surrounded the design of our patent/copyright law. Namely that the difficulty in making duplicates of things behooved would-be publishers to obtain the help of the author before doing the publishing.

Regardless of how you feel about yourselves ... you may be very upright moral people and would never think about violating intellectual property rights ... there are people out in the world who feel differently about these things. It's their computer and they don't want to give control over it to some other program/they don't see the point of paying $100 for a floppy disk/they like getting away with whatever they can possibly get away with/whatever.

This is a subject which comes up repeatadly. There is no solution within the current rules of patent/copyright law because there is no possible enforcement. (And don't tell

me about copy protection schemes ... I have never seen one
which did not leave as good a product afterwards ... i.e.
you either have a more difficult product to use, or it's
buggier ... This even applies to other media, books printed
in blue so they can't be xerox'd, vhs tapes with macrovision
encoding that makes the picture a little bit worse and doesn't
even work in all vhs players, the proposed copy protection
for DAT tapes that'd take out a notch from the audio spectrum
needlessly, ad nauseum)

Please ... I plea for one of two things.

Either 1) you shut up 'cause the subject has already been haggled
out in many newsgroups already nobody has come up with
a satisfactory solution.
2) You come up with something original to add.

People who are interested in where I'm coming from read:

The various writings of Richard Stallman about the Free Software
Foundation.

The July '85 issue of Whole Earth Review. It's the one with
the picture on the front of 3 flying saucers flying through
downtown San Francisco, and has a couple of articles about
digital retouching of photography. The article raises most
of the points I'm thinking about right now.

A book by Stewart Brand called _The_Media_Lab_. You'll find
it in your local book sellers ... it's non fiction, black cover,
a white light holography on the front cover. The book is
about the MIT Media Lab and the work they're doing with making
a new media and re-designing how people live with technology
and so forth. It's also made me really want to work in the
media lab for awhile ... :-)

I don't see how the current system can continue functioning
for very long. Some new sort of software (and other intellectual
property) distribution system will have to be constructed
before very long. Possibly as part of the coming economic
crash which will likely be here after the elections?

Shareware was a good idea in this regard.

Well, to be fair, it does make a much 'prettier' looking manual (as is TeX's wont) -- including much more legible tables, particularly where 'non-ASCII' characters are involved, as with the accented chars.

Also, I have a feeling that the takeup of TeX is higher in Europe, which may have influenced the decision. Still, an alternate form for us poor folk would be nice.

Neil,

I'm looking for Atari dealers near Santa Barbara, CA (or Goleta) that would carry the 1040ST or Mega. (Even the Ventura/Oxnard area would be reasonable.) Are there some? Could you send me some names, addresses, and phone numbers? Thanks much.

Cheers--

If the version of krabat you have is v1.1 (if it's higher, could you
pleeeease send me a copy :-)), and you *didn't* get it from atarinet or
listserv@canada01, then the pictures should probably go into PICTURES.BW
or PICTURES.COL, depending on whether you're running in high or medium
res. If you *did* get your copy from one of the file servers mentioned
above, try putting everything (pictures, openings, etc.) in a folder KRA
(or KRAB, I can't remember which) in your root directory.
Why the difference? A friend of mine sent me v1.1 about a year ago.
I didn't like having the files hanging about in various directories, so
I used a disk editor to hack the program so it searched for all the files
in one directory. I subsequently posted copies of that edited version to
atarinet and listserv. That was probably a no-no, but I neglected to keep
a copy of the original, and it didn't seem worth the trouble to change it
back. (Besides, that was back in the days when everyone was living in mortal
fear of the DREADED 40-FOLDER BUG. :-))
BTW, has anyone had any problems with krabat1.1 running in color? I
run it in high res, and it's never so much as dreamed of cheating on me,
but some friends of mine with color monitors claim the program is bug-
ridden.

We're talking "here's the chips, now get them installed". With all the
various boards out there, it seems that there was no better solution.

Pricing is not yet finalized, but should be around $120.

1220. Wanted: Assembler example with timer interrupt

Newsgroup: comp.sys.atari.st
Date: 1988-01-19 20:05:25 UTC
From: gdr@pbhya.UUCP
Message-ID: <8502@pbhya.UUCP>
Source record: 255020

I am writing some music composition software. I want it to spend most of its time making up music, but then at regular intervals send the next note (or note-off message) out the MIDI port. I have read what ST Internals has to say about the clock interrupts, but since there is no example given, I am still murky about what I need to do and in what order. As I understand it, using the C timer, I am limited to intervals that are multiples of 1/200th second. Is this true? Also, I remember reading here that the 200hz clock is not always accurate. Is this so? And why? I understand that I have to mess with a vector, and then write a routine (that sends notes) at the place to which the new vector points (I assume by using another ORG in the assembler code?). But... how do I make sure that after that routine is done, the main part of the program continues exactly where it left off?

I guess what I need is an example of code that uses a timer interrupt, or else a clear, thorough book on interrupts. Any suggestions?

1221. Quick hard disk questions

Newsgroup: comp.sys.atari.st
Date: 1988-01-20 00:35:00 UTC
From: FXDDR@ALASKA.BITNET
Message-ID: <8801200537.AA26097@ucbvax.Berkeley.EDU>
Source record: 255021

Two questions about hard disk use. First the generic one:
1. What is the proper order to stick the files in the auto folder (booting off floppy) if I want to have GDOS, FOLDRXXX, a ram disk (Eternal, probably), and the hd boot program? (I wish Atari and Supra would talk about such things in the docs...)
2. The Supra drive has PARK.PRG to park the head. The manual says "the program automatically parks the drive's head and instructs you to turn off your system." When run, the program says "SCSI parking" and the motor shuts off. Then it says "Searching" and does nothing for several seconds. Then it goes back to the "SCSI parking" display (motor still off) and displays an ABORT button...and that's all. Never instructs me to turn off the system. May one safely assume that the head is in fact parked when the ABORT button appears? I guess I could give the box a brisk shake and see if anything rattles...but I'd feel a lot better if I knew the head was well and truly parked before I move the drive.
Thanks,
Don Rice

>
> --j.a.tainter

Well, I would suggest that you open the case and try to re-seat any socketed chips in the drive controller (Atari rule of hardware #1 ;-)). If that fail to help (I really don't think that it will), you may have discovered Atari rule of hardware #2: Never, under any circumstances, allow more (power, buffering, current, memory - you pick one ;-)) than absolutely necessary. It seem to me, after looking at some of the hardware designed by Atari, that they know very little about power supply design. In almost all cases, they have chosen a power supply that will just barely (on a very good day) supply enough current to drive the given hardware. It sounds to me like the hard drive is sensing the power drop-outs, and is attempting to re-initialize. I could be wrong here, but I would try to get a stronger supply and see if the problem goes away (any PC power supply will work fine - I've gotten tired of the Atari power problems and have re-packaged my entire ST - floppies, hard drive, system board into a PC/XT case plus supply. This improved the overal performance of my system markedly - no more unexplained crashes, I don't have to boot it 3 times to get it to come up once, etc.). I hope that these suggestions will get your hard drive back on the right track - no pun intended.

Source record: 255024
Cross-posted to: comp.sys.amiga,comp.sys.misc,comp.sys.ibm.pc,comp.sys.mac,comp.sys.atari.st

Ok, I'll come up with something original.
The problem is capitalism.

I hope this doesn't make me sound like a dogmatic Marxist (I am neither),
but I still feel that capitalism is the problem: people want money back in
return for their efforts, and aren't satisfied with fame or esteem or whatever
else.
Now, that is reasonable if you make 'hardware': a knife is a knife even if
you don't want to share it. But, it doesn't work for ideas. If I write a
beautiful song, but I don't sing it (or, preferrably, let others sing it:-)
in public, I might as well not have written it in the first place. It's value
is in publication.
The same is true for books, philosophies, ideas and (to a certain extent)
software. In this case, I mean the type of software that everyone copies:
games, utilities, all the nifty stuff that you would probably not buy
otherwise. It is probably different for a tailored account program for a big
firm (but who would want to copy that).

I think the GNU people are on the right track: give the software away free,
so that people become to know and love it, and if you want to make money
you charge for other things: support, documentation, training, etc.

Neil,

Care to comment on this???

In the January issue of Unix World it is stated that Sig Hartmann says
a 68030 based machine that will run UNIX System V is in the works and
WILL BE AVAILABLE IN 1988.

But then again, the same article says the ST uses a 68010...

>It appears to be corrupting its ramdisks in some obscure way. Anybody
>seen this? Anybody got any ideas?

First, as usual, check to be sure you have removed all /AUTO programs
except the hard disk driver, and any accessories. Be especially careful
of accessories which do not register themselves, such as those associated
with DESKCART.

Second, be sure you have the most current version of TURTLE, which is 2.16.

Your problem sounds like those which occur in one of two situations:
1) some accessories and /AUTO programs take more memory than you can spare
and still get all the parts needed for TURTLE into memory (TOS, RAMDISK,
TURTLE, Screen, etc.) Others (such as the Control Panel) cause some
errors to occur well after things have been running along.

A last ditch effort to get around the problem: After removing all the
other /AUTO programs, place the proper TURTLE RAMdisk into the /AUTO
folder and re-boot your system. This allows more RAM for TURTLE and
TTLEXEC to execute. See the TURTLE documentation for which RAMdisk
to use. Using this technique, I can run Beckemeyers Hard Disk Accelerator
with 16K of buffers and back up on double sided TWISTER format disks.
(The accelerator is also in the /AUTO folder, before the RAMdisk.)
Your results may vary.

2) One of two bugs which were fixed in 2.16 may have bitten you.
When there are large enough files imbedded in folders to exactly fill the
RAMdisk in less than 15 files (without overfilling it), the imbedded
folder in which they reside is split across multiple floppies, it
is the first folder on the current disk, and it is more than two levels
of imbedded folders deep, TURTLE had a wrong total of free space in the
RAMdisk (got all that?).

When the root directory is filled, but there is space for another
file in the RAMdisk, TURTLE tried to write the file.

Both these bugs were fixed in 2.16.

If I haven't given you a clue to your problem, contact me directly and
we'll see what may be happening. You may have found the elusive last bug....

From: brenes@sky.COM
Message-ID: <219@sky.COM>
Source record: 255029

Try looking at the MWC (Mark Williams C) manual. It shows some examples of using the timers to interrupt a program. I would recommend to use timer A which is reserved for user applications rather than timer C which is used elsewhere in the system. Also some of the examples that come with the package deal with handling system calls from a C language program. I hope this gives you some leads.

A few hours after this posting, I discovered that Tim Oren's
Pro GEM column 13 contains source for a modified form_do, which
I think should do the job.

No need to send me code. However, if anyone is aware of any
bugs or caveats concerning the Tim Oren form_do, please let
me know. Thanks again.

Hard to buy a house with esteem or fame...same goes for lunch. You
can't eat money...

> Now, that is reasonable if you make 'hardware': a knife is a knife even if
> you don't want to share it. But, it doesn't work for ideas....
> In this case, I mean the type of software that everyone copies:
> games, utilities, all the nifty stuff that you would probably not buy
> otherwise.

Nope. Software is not an idea any more than a knife. You can have
and idea about "knife", but the application of that idea, involving
resource (materials, energy, tools, skill,...) is all tied up in
producing the knife. A program (game, utility, demo, whatever) needs
not only the initial concept (idea), but the programmer's tools for
development, hardware to run said tools, time, ... This doesn't cover
overhead such as shelter, food, and whatnot. Who's going to suport
me while I'm producing this thing, whatever it is? (Usually, I
work full-time for someone else and do it in my spare time. Whatever
that is.)

> It is probably different for a tailored account program for a big
> firm (but who would want to copy that).

Why? (Not about copying it!! :})

> I think the GNU people are on the right track: give the software away free,
> so that people become to know and love it, and if you want to make money
> you charge for other things: support, documentation, training, etc.

People seem to value something more-or-less in proportion to what
it cost them (in money, time effort, whatever). Note the general
treatment of shareware: People get it for free (or for minimal effort)
and very seldom do those who keep and use it ever pay *anything* for
it. Which, besides being unfair, is dishonest.

The GNU people (particularly Mr. Stallman) might not continue with
their idealistic ways if they had no other source of income beside
the software that they're working on. (Who's paying their bills?)
Is TANSTAAFL false? (Seems to work most everywhere else, except

in politics.)

On the other hand, as a technical writer, I think that charging lots for documentation is a pretty nifty idea...as long as I get my cut. (Comes the revolution, comrade...!) But who needs much documentation, support, training, etc. for "Defender of the Crown"? If such were really needed and used, do you have any idea of the size and cost of a really useful support organization? (Hint: >>More than what is currently needed to write, package, market and distribute the product as it currently stands.)

Nice-sounding idea, except that software is more than just an idea...

1234. Re: SH204 and MS-DOS

Newsgroup: comp.sys.atari.st

[]

I got hold of the fix from Avante Guarde to make MS-DOS correctly read
the Atari SH204 hard disk under PC-Ditto. Turns out that the boot
parameters in the HD are trashed after running the Atari utilities.
Here are correct values of the trashed parameters in logical sector 0
of each HD partition: (the trashy ones sure looked suspicious!)

correct trash

NFATS 02 20
MEDIA F8 73
SPT 0011 2E70
NSIDES 0004 2C73
NHID 0001 2076

(all in hex). I also put F8 in the first sector of each copy of the FAT
in each partition, just in case (the fix program from A.G. does not do that).
They say you must fix it again after EACH TIME you run HDX or HINSTALL.
(Oh, BTW: where in the world am I supposed to get HINSTALL and SH204DVR.SYS,
the official (?) Atari HD boot stuff? The SH204 I bought was shipped this
fall with only AHDI and HDX. In contrast, Supra supplies a very nifty HD
sector editor.)

I was hacking away and found that this gulam file crashed gulam. Does anyone have any ideas on how to do this.

```
if -e $MAN_LIB$1.man
more $MAN_LIB$1.man
ef
echo No man entry for $1
endif
```

I can see the file and then as I exit the shell crashes with 2 or 3 bombs.

I have set MAN_LIB d:\man\ in gulam.g.

TURTLE does not back up a file that does not fit on a floppy. This could prove to be a severe limitation. Has anyone hacked this or done anything about this.

Source record: 255038

Recently I sent a letter to the net I had received from Skip Tavakkolian.
It described various features and characteristics of IDRIS. One most interesting feature was the emulation of an MMU.
I added a few questions, which I'd like to repeat and perhaps make them more concrete, because I haven't got any response.

>- An emulated MMU seems a good idea if there is no hardware. But doesn't that
>make the OS very slow?
I'd greatly appreciate to see any benchmarks. In particular I'd be interested in "standards" like dhrystone/whetstone. If someone has run these on the ST under IDRIS and/or OS-9 *PLEASE* write the results either to the net or directly

to me.

>- Any experience with porting UNIX software?
Has anyone done a *really* tough thing under IDRIS or OS-9 (like compiling GNU Emacs or UNIX Emacs, these being an example only - experience with any other interesting software is welcome)? I'd love to know.

>Does anybody know whether IDRIS is available in Germany?
I still don't.

Thanks in advance

> (etc.)

I've run into this one before myself. If you read K&R carefully, two structures can have components with the same names *only* if the components are of the same type and at the same offset from the beginning of the structure. Many C compilers have departed from K&R and fixed this particular brain damage long ago -- I've been told that the ANSI C standard does not impose any similar restriction.

It would be nice if Alcyon at least provided a warning about duplicate component names, but C has never been known as a language that provided good compiler diagnostics....

1240. RE: Multiuser Bullettin(g?) Boards

Newsgroup: comp.sys.atari.st
Date: 1988-01-21 01:09:00 UTC
From: EDSTROM@UNCAEDU.BITNET
Message-ID: <8801210330.AA18012@ucbvax.Berkeley.EDU>
Source record: 255040

This pertains to the STadel/multiuser BBRD discussion:

First: Neil, I think that you may be missing something with the discussion on STadel. A number of STadel users have written in and actively promoted its adoption by Atari. That no one has been pushing other BBRD packages may reflect the fact that commercial concerns are discouraged from pushing their products on the net. Even so, I can't recall any USERS of other BBRDs sticking up for any other product.

Even if STadel doesn't behave the way you think a BBRD ought to behave there are a number of users out there who are enthusiastic about STadel and motivated enough to make it work and even write friendly tutorials. The point is that there is a significant user/owner group out there who do want it and the goodwill and desires of a significant user/owner population are not, or at least should not, be taken lightly.

Second: Sorry, STadel-enthusiasts, I tend agree with Neil that as it is now STadel is not suitable for his needs. The major deficit is the inability find public messages. Citadels' strength is chat but makes it difficult to read some particular messages. For example, to find and read a message that you remember having read once and want to re-read, you have to go through all of the intervening messages first and scroll back to it, you can not go directly to it.

I don't use that feature often and enjoy and prefer the speed and ease of navigating around a Citadel-type board but on a commercial board where one expects callers looking for specific information this is an important deficit.

Third: The built-in networking in STadel is an important feature as is its price, i.e. free. This gives any user the option of participating directly in an Atari (and some other brands) computer network.

With a little organization and forethought the need for a multiuser BBRD might disappear altogether.

I would go so far as to suggest that Atari even consider bundling STadel with new computers. This would give new users an opportunity to participate in a rather large and usually friendly user community and, if Atari adopts STadel, Atari-central itself.

Fourth: STadel is not a multiuser BBRD. It has been suggested that its networking capability could be used to keep the various rooms on the various computers more or less up to date. This is an ugly notion but true. I suggest that the built-in networking in STadel can be modified to use the MIDI lines continuously so that each incomming message or file is available to all of the STs in the ring. Obviously this is not a

feature that the average home user would want and is apt to be added,
if at all, only if Atari seriously considered using STadel.

Fifth: Someone wanted to know what was wrong with Forem. I have used
it a lot (not as an operator but as a user) and have no serious
complaints. Its a fairly standard multi-featured BBRD program that does
most of what you'd expect a BBRD to do. It contains the message-finding
utilities that STadel lacks. My criticism is that you can't escape
them and I find that annoying. Most of the time I don't care about
those features so that when zooming through a bunch of
mail or entering a message there you are confronted by menus and
sending mail is like playing 20 questions.

I would really like to be able to turn them off when I don't want them.
I consider it one of STadel's virtues that it defaults to the zippy mode
and the more baroque features are only invoked by explicit command.

1241. Atari Policy for present owners

Newsgroup: comp.sys.atari.st
Date: 1988-01-21 01:49:00 UTC
From: MOLCS@UNO.BITNET
Message-ID: <8801211524.AA02102@ucbvax.Berkeley.EDU>
Source record: 255041

Neil Harris,

I have a 1040 ST and would like to know what options are available
to me. My local computer center will not sell any Mega's sans monitor,etc
To see a Mega system I have to travel out of town, to get one I need to
special order one ($$$ upfront) from the local computer center...

What I want to know is: Will Atari sell a minimum Mega system to those
520 and 1040 owners who already have Monitors and external Drives at a
special rate? Will you (Atari) sell Mega's at the normal rate without
the monitor (..etc)?

I really would like to stay with Atari in the future, but Atari's
present system of making promises (claims, announcements) and not
fulfilling them is driving me to consider switching to a different
vendor in the future.

NOTE: I, being a CS student, will certainly be buying equipement for
myself, perhaps for a company, and recommending purchases to friends
in the near future. What can Atari do for students and people to
maintain vendor loyalty?

Michael O. Lott

Very nice in principle, but:
1) Do you have any idea how much work goes into even things like
games and utilities? (10 man years for Falcon, God knows how much
for something like MPW).
2) Have you ever tried to buy groceries with fame or esteem or whatever?

Writing good software is a full-time profession. People not only won't, but
CAN'T do it if you don't pay them to. Most people don't need support for
things like games and utilities- the only way to make money writing this kind
of software is to sell the software. Copyright laws exist to allow people
who write such software to make a living doing so. If the laws didn't exist,
neither would the software.

> read/drive error.

The vbl routine that does floppy-disk deselection checks if the DMA
chip is in use. If it's busy, the vbl can't do the deselect.

Also, some drives don't return INDEX pulses unless a disk is inserted.

> Unlike MS-DOS system The ST looks for a BOOT sector first at the Cartridge
> Port then on Drive A, Drive B then it looks for a Boot sector on DMA Logical
> Unit 1 (The Hard Disk), If it finds a boot sector on drive A it boots drive A
> and If It Does not Find a boot Sector on Drive A it looks else where until it
> finds a Boot Sector. When you Instal AHDI you are actually installing a Boot
> Sector on the Hard disk.

Not quite. The startup sequences goes more like:

<various ways of starting up a cartridge, too baroque to mention here>
<attempt to boot from drive A>
(it might load and execute code, then continue, or it could
take over the system)
<attempt to boot from ACSI devices 0..7>
o the first one "wins", because:
o non-blitter ROMs have a nasty boot bug that causes the
system to lock-up when reading device 1, if device 0
exists. "Fixed" by boot-stopper code written to device
0's boot sector that halts booting on the first device
with this code.
<run the AUTO folder on the boot drive>
<bring up the desktop>

In bootable AHDI, the last two steps are actually performed by the
driver loaded from the hard disk. I also forget when RAM packages are
executed (just before the AUTO folder, I think) but I know that they
don't happen with AHDI, but they do with the ROM. Allan?

AWK! Consider:
The only way the same program can load into both machines is if it is
loaded at boot time (file systems are different, so loading by dos is
not possible).

This means you have to reboot to use it. Thats fine for a single tasking
computer like the ST, but a no-no for the Amiga.

1248. free multitasking kernal

Newsgroup: comp.sys.atari.st
Date: 1988-01-21 13:17:33 UTC
From: nfrech@ALMSA-1.ARPA
Message-ID: <8801211400.AA00529@ucbvax.Berkeley.EDU>
Source record: 255048

I would like to cast my vote for a free/pd multitasking kernal!!!

Along this line, would stand alone applications such as publishing partner be able to survive in the multitasking environment or would applications have to be specifically written for this kernal? I use a 1040 with publishing partner and I would like to be able to switch back and forth between PP and a text editor without having restart each application. Multitasking seems like the answer to me.

1249. 1040 to TV/VCR

Newsgroup: comp.sys.atari.st
Date: 1988-01-21 14:01:00 UTC
From: brantly.henr@XEROX.COM
Message-ID: <880121-060235-4965@Xerox>
Source record: 255049

FYI,

I followed up a pointer from Neil Harris & called Practical Solutions to request info on their adapter to convert the RGB outputs from a 1040 (non-rf modulator version) to composite & rf signals.

They plan to have the device in the marketplace within 6 weeks, they assure me that it is NOT vapor-ware. The current delay is the wait for final FCC approval.

This device is to retail for $119.00, will plug directly into the monitor port of the 1040, and will produce both composite & RF outputs, thus enabling connections to a TV/VCR.

This should allow 1040 owners to video tape their sessions, and (this is what I really want!) monochrome owners to hook up color TV's to check out the low rez and med rez stuff they've been missing out on (without having to go out & pay $350+ for a color monitor).

In case anyone wants to call Practical Solutions in Tucson for additional info, their # is 602-884-9612.

Thanks to Neil for the pointer......

Dennis....

1250. Mega vs 1040ST

Newsgroup: comp.sys.atari.st
Date: 1988-01-21 14:04:00 UTC
From: gaspar@ALMSA-1.ARPA
Message-ID: <8801211429.AA01062@ucbvax.Berkeley.EDU>
Source record: 255050

I know what the basic differences are between the Mega and the ST line (keyboard, memory, blitter, etc.) However, I was considering recommending the Mega to a novice user and happened to mention it to a dealer (probably a bad choice :-)). He made the comment that since the 1040ST was in its 17th revision (his terminology) it was a much more stable machine than the Mega, which had just been released. He went on to say that if a bug free working environment was the priority, one should stick with the 1040ST (and who would EVER want 2meg :-)). I can follow his thinking, but I'm not sure whether it is based on true experience or just hypothesis. Obviously, though the Mega is a new machine, it is based on the earlier ST line. Anyway, does anyone with experience on both machines give any credence to this dealer's comments?

Cheers--

Al

I'm new to this discussion so this maybe an old answer, but I think that part of the problem is the cost of the software. Suppose someone wants the new hot shot program "Foo Bars Baz", but doesn't feel like it is worth $50,$100, or $500, so he waits and hopes the price will come down. Then someone he knows offers to copy it for him. What does he do? He wants the software, would really rather buy it, but here it is free and easy. The odds are very high that he will have it copied and go on. Now what would have happened if the software had originally cost only $10? The person would have probably bought it when he first saw it. I have no idea if any software product could turn a profit at $10 a pop, but the high prices of software are a contributing factor. For example, nobody ever copies something out of a $3 paperback, but many $50 textbooks have parts copied out of them all the time. I feel like most people are basically honest (Were did I get the rose colored glasses? :-)) and will buy things and pay the appropriate price, if the price is what they consider to be reasonable.

Of course, even if I'm right, I don't know a good solution. I hope that software houses aren't making obscene profits on their stuff, so I would think that lowering the price would be almost impossible. Oh well, at least this can be food for thought.

I just thought I post what it cost me to produce a copy of the FoReM BBS
system:

1) disk and label $2
2) user manual $6
3) royalty to maual author $2
4) packaging $5 (plastic case and insert)

Now, this is only $15. Add to this, promotional materials, cost
of support bbs, cost of advertising, cost of returning phone calls...

Now, subtract that from the $24-$27 that distributors pay me for it
and you can see that I'm not getting rich, especially when you consider
how many paying customers there are for bbs software (hint: not many).

Odd, isn't it? Some people actually want to pay the rent, and save for
their retirement, and go on vacation occasionally.

A company I used to work for had a General Manager who told us one day
that working in Engineering was different from Marketing or Sales because
there was "psychic income" from being creative. Alas, stores don't accept
"psychic income" in exchange for tangible goods.

> Now, that is reasonable if you make 'hardware': a knife is a knife even if

Huh? If your motivation is fame or esteem, very true. But most people are
motivated by a desire to live a more comfortable life -- not to be center
stage.

> The same is true for books, philosophies, ideas and (to a certain extent)

> otherwise. It is probably different for a tailored account program for a big
> firm (but who would want to copy that).

Wrong. The stuff that gets pirated include word processors, spreadsheets,
data base managers -- that's why there's a major industry producing books
about the more popular software products that replicate the content of the
manuals -- frequently with no other additions.

> I think the GNU people are on the right track: give the software away free,

> you charge for other things: support, documentation, training, etc.
>
> Jack Jansen, jack@cwi.nl (or jack@mcvax.uucp)

But if esteem and fame are enough for software, why not support, documentation
and training? What makes software different from these other categories of

human endeavor?

Well, if a window for a hard drive partition is open, the desktop will try
to read the directory for that partition when the PARK program exits.

And if the desktop tries hard enough, you may undo the park process. Enough
seeks _will_ unpark the head on certain drives (on my micropolis, anyways).

Ah well, *my* favourite rumour (from a humourous 'predictions for 1988 column')
is that sometime in 1988, Amstrad will file suit against all the other micro
manufacturers, on grounds that their 'screen and keyboard' hardware arrangement
infringes on the 'look and feel' of Amstrad machines. (All other makers will
begin working on new designs, based around the abacus.)

Wanting money back in return for efforts, and/or not being satisfied
with fame or esteem, has nothing to do with capitalism. This belongs
in the realm of psychology.

Capitalism has more to do with whether it's legal to obtain money in
return for one's efforts. The GNU project fits perfectly in a
capitalistic system, as does shareware and public domain software, as
does commercial software.

A friend of mine would like to know what good LISP compilers
exist for the ATARI 1040ST. He would prefer Common LISP but
will settle for information on any good LISP implementation.

He did not mention whether or not (or how much) he is willing to pay, so
I'll be interested in hearing about both commercial and PD products.

I neither own an ATARI nor program in LISP, so I do not read these
news groups. Please reply only by mail. If I get a lot of requests
I will post a summary to comp.sys.atari.st and comp.lang.lisp.

In article <39450@sun.uucp> fiddler%concertina@Sun.COM (Steve Hix) writes:
<Note the general
<treatment of shareware: People get it for free (or for minimal effort)
<and very seldom do those who keep and use it ever pay *anything* for
<it. Which, besides being unfair, is dishonest.

Dishonest? Unfair? I'd suggest you look in a dictionary. For instance,
the OAD says that dishonest is merely not honest, and that honest is:

1) truthful, trustworthy
2) showing such qualities
3) got by fair means

Now, someone *gives* me (or otherwise makes available at no cost) a
piece of software. I haven't done anything dishonest so far. They then
say "Give me money if you use this." I *still* haven't done anything
dishonest.

As for fair, that means according to the rules. The rules (laws) in
the US state that if you give somebody something, it's *theirs*. You
can get neither payment nor the return of the thing, unless there's a
prior agreement about such.

Now, calling such people immoral and disgusting is fine. Those are
value judgements, and I can't dispute them. Of course, I expect the
same when I tell you that I find the very concept of shareware immoral
and disgusting. I mean, you give somebody something, and then tell
them they are immoral scumbags if they don't pay you for it?
Especially when in many cases someone else is willing to give you the
something very similar without calling you names if you don't pay for
it.

I downloaded the uuencode.c and tried compiling it in Alycon C and Mark Williams C. Alycon C just hangs up, while Mark Williams does an exit #2, USAGE error. Has anybody been able to get this to work with the compiler's I have? I tried the UUENCODE.BAS using the ST Basic I got with the ST, and that runs the program, but doesn't do anything. Anyhelp will be appreciated.

Also, assuming I get a uuencode.prg working, i notice there sometimes are directives at the begining or end of the .uue files. Are these left in? Exactly what should be left in in when I edit out the headers?

I did see the Computer Chronicles about the Comdex show about three weeks ago and thought they did a good job of covering Atari. They talked about the Abaq, the CD-ROM and the Laser Printer as well as some of the desk top publishing packages as I recall. Move coverage of Atari than I have seen in a long time.

On an unrelated issue, Neil, what did you guys do to tick off Activision? They are not only dropping coverage for us 8bit users (not unexpected :-( ) but also for the ST. Infocom (an Activision subsidiary now) is not going to write any more games for Atari period. What gives? How hard can it be to port their text adventures for the Atari machines? After all, it is mostly just formating text for the screen (except Beyond Zork, which is supposed to have some nice ST graphics support). I have bought several of their games for the 8bit and so have many other users in our User Group. Are we the only ones? Can sales really be that bad? I find it that hard to believe.

From: UUCJEFF@ECNCDC.BITNET
Message-ID: <8801212259.AA12811@ucbvax.Berkeley.EDU>
Source record: 254962

Someone asked about using Beckenmeyers C Shell. First off, it does not emulate the Unix system. It is more properly described as MS-DOS in UNIX clothes, if that. I like it though, I hate to have to do OS type stuff using the silly desktop. For one thing, you got wildcards.
It is also easier to use *.ttp files, you dont have to waste time opening batch.ttp, and you enter the arguments the normal way.

I think Mark Williams msh has a few more features, I have only just started using msh, so i cant compare them. But if you dont have Mark Williams, I would recommend Beckenmeyer's. It makes things a lot easier.

<neither would the software.

Matt, I don't know what drugs you've been doing, but you should stop. It's causing you to overlook some important facts. Let's look at the tools I use, from the ground up:

OS - it was written by a couple of people working for a company that was forbidden *by law* from either selling or supporting it. Further enhancement was done by a seperate group that has been giving it away for the cost of time & materials, and may be required to do so by law (4BSD).

Editors - two of the four I use come gratis with the above OS. The other two are available to anyone for the asking (ed, ex, GNU Emacs and microGNUEmacs).

Languages - one comes gratis with the above OS; one I had to pay for; two were free for the asking (C on 4BSD & a PC, CScheme & T).

The software that manages the bbs-like system your message & this reply appear on is free. The software I use to access that is free. Free software is available to talk on the networks it travels over for a wide variety of hardware.

Further, some of the best programmers I know (people who write working device drivers without having hardware to test them on) don't write software for a living. They maintain software for some group that needs it to get their work done - and are allowed to give away their changes and improvements to that software, and any tools they write to make their job easier.

No, copyright law - or lack thereof - isn't why software gets written. It gets written because people need it, or because they want it. All the copyright laws really do is restrict the distribution of the software once it gets written.

With all the problems with pirating software I wonder why do some
people still make commercial programs? I can understand utilities and
productivity software can make money because people need them, and their
docs; And with the typically inflated prices, they still can make money.
As for games, I don't understand why anyone would put in the effort if they
know it will be pirated.
I think back when computers were new, people loved it when a new
game comes out. If it was good, people loved it more. Being unsophisticated
people didn't even think of copying programs. But later, the market
was inundated with games and copy utilities came out at the same time.
Nobody could hope to buy every game, and not all of them were good. Face it,
most games aren't worth the money to buy them. But some were good and got
lost in the crowd.
I personally tried a lot of games, but the few in my collection
keeps me happy.
But enough of my thoughts, I still don't understand why new games
still come out, even if they are worth the price, few people will actually
buy them.

Comments welcome.

Moshe,

would you please inform as to what SUPEDIT is? I was born under a rock.

In reference to Atari hard disks in general, is there an equivalent of "chkdsk"; i.e. a file system consistency checker, fixer-upper anywhere, available for the average atari owner for rent or purchase? Mr. Harris, not having such a utility provided with your system is unfathomable.

Also... I have an atari SH20? hard disk and am using the driver supplied. Unfortunately for the sake of atari it sits next to a zenith 150-pc clone running good old msdos 2.2. Said ibm machine has a NEC 20meg drive and a 1010 winchester controller using the driver buried away in the bios or somewhere. "To make a long story short, too late, said the man in the audience...", My klunky old pc beats the atari's performance on disk writes to pieces. This is curious. The pc disk is currently fragmented beyond belief with about %90 full; i.e., I won't buy any reformat and try again explanations. Reading seems to be comparable. I recently put together a little piece of code that was the equivalent of the unix find utility and read all the directories on my 15 meg C: partition. That was fairly speedy. Writing is another matter. Why? Flicking the bit that turns off write-verify for "floppies" doesn't seem to do any good on the hard disk. Did the supra driver that Moshe used do any good on the atari disk?

One other observation:

As a rough benchmark: I have an interpreter that I run as a standard time test on about an 8k "src" file. This program exists on both pc and st. It should be compute bound as it really doesn't spend too much time reading and writing to disk unlike say your average 4 pass C compiler:

on ibm-pc compiled with usoft v5.0 C

.30 seconds to compile (read compute write)

on pc with all file i/o via ram disk

.26 seconds to compile (read compute write)

on atari using SH20? drive and MWC v2.0 C compiler

.30 seconds to compile

on atari using ram disk

.15 seconds to compile

At least the 68000 computes faster...:->

I think that the laws state that you can not be required to pay for unsolicited
stuff that you get in the mail. But you do not get to keep the stuff.
Of course, I'm not a lawyer. This is just what I've been led to understand
by people who have received (for example) unsolicited magazine "trial
subscriptions".

> ... I find the very concept of shareware immoral
> and disgusting.
[Above taken grossly out of context]

Fine. Don't use shareware.

> Especially when in many cases someone else is willing to give you the
> something very similar without calling you names if you don't pay for
> it.

Then there's no problem. Don't use the Shareware stuff. Just use the free
programs that people are standing in line to let you (you wonderful guy you)
use. Continue to sponge off the hard work of people around you. Continue
to refuse to give payment for value received just because the person neglected
to wait until your check cleared. Be a man and don't give in to the blatant
extortion implicit in shareware. America will be proud of you for it.

An important argument for buying or not buying is the amount,
quality and price of the available software.
The main reason why our university is buying Atari ST computers
was and still is the availability of free quality software,
especially the fantastic Uniterm, written by Simon Poole.
I think Atari should be aware of this fact (how many thousand
Atari ST have been sold because of Uniterm?) and support those
people who are providing us with such good software.
Hint: Atari, give for example a color monitor to Simon,
he really deserves it.

I also think that Atari should take the following letter from
David Beckemeyer very seriously.

> Say if a multi-tasking TOS compatible kernel were
> available free to all users of the ST. In other works a free
> runtime-only kernel to anybody that asks. Maybe even Atari gives
> it aways with each machine. Programs developed for the multitasking
> kernel will run on any machine with the free kernel installed.
>
> End-users get the runtime kernel free. Developers pay for a "development
> kit" that includes non-PD documentation and programming language interfaces.

Atari, this is the best opportunity to introduce multi-tasking
into TOS. Please support this guy.

I don't think that $50 or $100 is too much to pay for (good) software. But when many companies charge $300 + for things like spreadsheets, that's where I draw the line. How can a company justify selling a piece of software for exhorbitant amounts of money, when another company can sell a similar piece, often with more features, for less (and even then make a hefty profit)?.

Don't bother to send me any mail regarding this, the questions posed are rehetorical, and I have no intention of arguing my point. Just wanted to vent some steam :-).

>down.

There is a significant difference between "PARK" and "SHIP".

"SHIP" exits after homing the head. TOS will then attempt to read the
directories and update the Desktop display. This causes trouble, since the
heads have been homed.

"PARK" never exits. You can run it from anything, with any windows open.
It homes the heads, then loops forever.

1280. Alcyon Return Codess

Newsgroup: comp.sys.atari.st
Date: 1988-01-22 13:39:51 UTC
From: woodside@ttidca.TTI.COM
Message-ID: <1725@ttidca.TTI.COM>
Source record: 254980

A few days ago, Allan Pratt of Atari offered to post the fixes for return codes from the Alcyon C compiler. I haven't seen them go by, so I looked them up from my old notes. I should note here that I made this change successfully when it was posted, but have long since switched to Mark Williams C.

This is from Robert Royar, March 12, 1987:

==========

About patches to the dev pack compiler/assembler/linker/relmod to return proper codes on exit. I poked around in the code and found the following (v 4.14 only). You should be reasonably familiar with SID and realize that some offsets are ballpark figures. So you will need to use the 'l' option to show you the instructions before you change them. Around 0xda from the beginning of each of the files (that offset is accurate if you load SID without a file and use the 'r' command), is a command sequence something like (it's been a while since I did the patch)

```
move.w #0,d0 ; return code
trap #2 ; old cp/m trap vect and new gsx
unlnk a6 ; Alcyon built-in patch space *8^)
rts ; useless return
```

```
the hex code is
30 3c 00 00 4e 42 4e 5e 4e 75
```

I changed this to

```
move.w #$4c,-(a7)
trap #1
rts
```

```
hex code
4a 9f 3f 3c 00 4c 4e 41 4e 75
```

The offsets are the same for cp68, c068, c168, and as68. The offsets for link68 and relmod are a little off from the 0xda mark, but easy to find using the l option in SID.

Hope this helps,

Robert Royar

==========

My note attached to that says that the patch actually reads

```
tst.l (a7)+
move.w #$4c,-(a7)
```

```
trap #1
rts
```

when you enter it as listed above, and that it worked as Mr. Royar stated.

Another patch note on Alcyon 4.14, from Jeff Reid, dated Dec 30, 1986:

```
==========================================================================

To fix the problem with static data and bss sections in a C program, patch
C068.PRG: using SID.TTP, read in C068.PRG using "R" command and at offsets
DEDD and DF25 from start base (use "H" command to generate absolute address)
use "S" command to change "60" to "7E" at both locations (start+DEDD,DF25).
This patch eliminates assembly time error when using static data or static
variables in a C program. (Patch changes ` to a ~, used to comment original
label).

==========================================================================
```

I never encountered this problem, so I never installed this patch.

```

> software once it gets written.

I think it's encouraging to see that some of the BEST software is free. I don't mean specialized applications software (e.g., CAD/CAM software), but rather general tools and programming environment software that everyone needs to do anything at all on their machines. Mike already mentioned a great operating system and the best editor [my opinion] in the world (GNU Emacs); I could add --

- one of the best word processing systems (TeX)
- one of the best state-of-the-art languages (T/Scheme)

and lots of other public domain software that we all use.

I don't know if I agree that copyright laws restrict the distribution of software though. The GNU distribution is governed by those same laws, and those laws have helped to ensure that the distribution remains free and easily accessible to everyone (without random people making money off it).

Message-ID: <1988Jan22.085124.4158@mntgfx.mentor.com>
Source record: 254983

Supedit from Supra is a maintainence/diagnostic utility that lets you examine/patch partition tables, boot sectors, etc. of ST hard disks.

In general, speed problems on ST disks (either floppies or hard disks) are caused almost solely by the fact that the current GEMDOS uses an INCREDIBLY! slow routine to search the file allocation table. (In fact, from the testing I've done almost the only way Digital Research could have written a slower search routine would have been to put in wait loops). The FAT is hit more heavily on writes which is why writes are slower than reads.

Hopefully the upcoming GEMDOS rewrite from Atari (when/if it hits the streets) should address the disk speed problem. (and it had better also fix the GEMDOS memory management problems. I'm really tired of the "40 folder" and the "20 Malloc" bugs...)

As another example I have a directory cloner that sits on top of a complete re-implementation of the GEMDOS filesystem (the only part of the ST roms I use are the getbpb and rwabs calls). While I don't remember exact timings, it runs a number of times faster than any copy routine built on top of GEMDOS and it doesn't slow down dramatically when writing to very full large disk partitions.

As to "chkdsk" functionality; both disk reorganizer packages I know about include a "chkdsk".

dgc

1284. vi on atari st

Newsgroup: comp.sys.atari.st
Date: 1988-01-22 17:13:12 UTC
From: jrb@dadla.TEK.COM
Message-ID: <2699@dadla.TEK.COM>
Source record: 254984

I called manx this morning about sw on the st.
Asked specifically about "z" (most of vi) and they
said that they expected to release a product in 4-6
weeks but they didn't know if they would bundle z
separately from their development kit (C, libs, the usual...).
Well the ad in the Jan. BYTE did say "call" and at
least it's an 800 number.
In the past one could get z separately at least for
msdos where it is a fairly reasonable vi-klone.

>
>Wrong. The stuff that gets pirated include word processors, spreadsheets,
>data base managers -- that's why there's a major industry producing books
>about the more popular software products that replicate the content of the
>manuals -- frequently with no other additions.

- that proves the original point: if the software is out there people can
make money on selling documentation. And who will pay the programmers'
rent? The company that plans to sell the books! Or perhaps the company
that plans to sell the hardware! Apple corp. is giving Hypercard away
(almost) even though it must have taken a staggering amount of work to
create. Why? To enhance the Mac's usefulness image ---> more HW sales.
Other options: a tax on blank disks could provide funds for public SW
writing efforts (a la Berkeley, MIT).

The overnight reductions of SW prices by 50% or even 75%, a common
occurence in the industry when competition hits, proves that some
high-priced SW _is_ overpriced and over-enriching the publishers. Most of
the retail price of SW goes to the retailer, distributer, advertisers,
etc.---NOT the authors. Since computers are so good at copying, leaving
the distribution to the users would save most of the resources and therefore
would make us all (_on_the_average_) better off.

- Moshe Braner

1286. Re: SH204 hard disk speed

Newsgroup: comp.sys.atari.st
Date: 1988-01-22 18:52:39 UTC
From: braner@batcomputer.tn.cornell.edu
Message-ID: <3472@batcomputer.tn.cornell.edu>
Source record: 254986

[]

As for SH204 writing slowness: that has nothing to do with the HW nor
the driver. It is a GEMDOG 'feature'. Notice when you write a file
to floppy how the head travels back and forth between the data track,
the (sub)directory and the 2 FATs at least TWICE? GEMDOS is wasteful in
such, and when the data gets far from the FATs writing many small
files gets very slow, even on the HD. No solution besides rewriting
GEMDOS. (When _reading_, with my own caching program holding the directory
and FAT, it is very fast.)

- Moshe Braner

PS: The ST desktop program is even worse than GEMDOS itself. To wit:
- when copying a small file from one disk to another in the same drive,
it copies into RAM just a few bytes (directory information, I think),
asks to swap disks, swap again, reads the file, swap again, writes.
(Why not copy all that's needed into RAM the first time around?)
- when copying a large file into a disk where there isn't enough space,
it first writes all that fits, then deletes it and says "no room".
(Why not check first to see if there's enough room?)
- when deleting a bunch of files in one operation, it goes back and forth
between the (sub)directory and FATs once for each file. In the time it
takes to delete one file clunky old MS-DOS can delete 40 files.
(Why not read the FAT into RAM _once_, do all the processing, write out?)
- no way to move a file from one directory to another without copying it,
then deleting the original.
(Micro-C-Shell does it the sane (not same) way.)

Since you asked... I'm afraid, I'll have to disagree with you. In the latest MacWorld (Feb. '88) Charlie Jackson of Silicon Beach Software fame mentions that sales of "Dark Castle" (an unprotected 'arcade-style' game) have reached approx. 30,000. Those are impressive sales figures for any one piece of software, game or not. From a personal standpoint, I certainly do hope that new, innovative games continue to emerge. I enjoy playing them on occasion (when I actually have some spare time!) and find that if it's well done, I'm more than happy to pay the $20-35.00 it might cost.

Message-ID: <2108@bath63.ux63.bath.ac.uk>
Source record: 254988
Cross-posted to: comp.sys.atari.st,comp.sys.amiga

I've gone a bit paranoid about cross-posting, but I would like to know what the answer is for both machines, so ....

Ok, here's one for y'all. Does anyone know of a terminal emulator running on the ST which will emulate an IBM 3270 terminal, speaking to the host system using Network/3270 (or SSMP)? We are aware of such beasts for the IBM/PC range, and for BBC micros ('what're they', I hear all the non-uk sites ask), so I thought, well, maybe...

Similarly, anyone know of such a beast for the Amiga?

Best reply address is whatever you can work out from the header. Failing that, the following should work:

Smee at UK.AC.BRISTOL (JANET)
Smee at UK.AC.BRISTOL via UKACRL.BITNET (BITNET)
Smee at BRISTOL.AC.UK (from ARPA, *iff* you can find a routing (via) which doesn't involve UCL)

Cheers, Paul

C Compilers for the Atari ST - Summary of replies

Well, this sure was easy. I got 4 replies, the voting as follows

Mark Williams C - 4 votes
Megamax C - 1/2 a vote
The rest (Alcyon, Lattice mentioned specfically) 0 votes.

Sorry to anyone who sent mail which got returned. We have problems involving a couple of problems with mail addressing from the NZ news feeder. Currently we are working on it, and eventually my address may be what is in my From: field (so sayeth the Guru across the desk from me :-) (-: Unix Guru, not mail Guru :-)

Much thanks to those who replied and to those who tried. The replies that got here were from
btb@ncoast.uucp (Brad Banko)
abi@dutinfd.uucp (Ton Biegstraaten)
preston@felix.uucp (Preston Bannister)
Mike Berkley <mberkley%watnext@watmath.uucp>

I'm glad I sent this out - so far, I have heard nothing in ANY mag about MWC (Mark Williams C), except adverts of course, so would have been loath to buy otherwise. However, I have been sold ...

Answers to the questions -
> How good is the documentation ?

All replies said that the documentation was excellent, to the point that Mike Berkley said "Some people recommend buying MWC instead of abacus books or the developer's doc."

> How good is the Debugger ?

The debugger appears to be an adb clone. No sdb (Symbolic Debugger), but there is mention of one in vapourware(:-)). Hopefully there will be one soon ?

> How fast is it ?

No real comparisons returned, except to Megamax, which lets you put the compiler on Ramdisk, so it runs faster. (Does this imply MWC will not run off Ramdisk Mike? It does come with a Ramdisk utility.)

> What is the editor / environment ?

It comes with microemacs, make and "unix-like shell with pipes and redirection (but no multitasking)".

> How good is the GEM interface ?

Complete library support for GEM

> How robust is it ?

Very robust. No noted complaints with MWC itself.

> How close to the K&R standard is it ?

It seems to cause very few problems in porting from a Unix environment, and
"complies completely with K&R, and has many of the ANSI extensions"

> What other products (C++, microemacs, etc) will run on it ?
> What other hardware does it support (68020, 68881, Stereotech Glasses, etc) ?

OK, I admit it - this is the optimistic section - I WANT an 68020 and
a 68881 in my box. And a Multitasking Windowing tool that I can access
from my software for my applications, but multitasking comes after the
MMU providing memory protection - I believe one of the custom chips
supports some MMU functions, but no-one seems to have multitasking of
the ground that I have seen. The Tower 1632 with a 68000 runs Unix
System V.2 - why doesn't my ST. Actually, I can guess. The 1632 is a
business box with an MMU without any graphics overhead. Still, it is
old technology. Enough spiel -

Compiled and working with MWC are the Gulam shell (?) and MicroEmacs 3.9.

What the Users want section.
Brad Banko (btb@ncoast.uucp) wants a "simple graphics library" so he can "write
simple graphics applications without having to endure the overhead of using
GEM".
Ton Biegstraaten mentioned the lack of RCS -> Revision Control System
(me thinks that's what the acronym is for).
Preston Bannister mentioned the lack of sdb.
Given I can't have The One True OS, all of the above make sense to me !

Thanks again for your replies

meg upgrade for 520stfm?

I recently bought a 520STFM and would like any information on
how to upgrade to 1meg on board (a do it yourself type job with chips
and sockets). We opened it up and looked at the mother board and
all the lines appear to be there for the next 512K like it is in a
1040. Besides the chips, are there any jumpers to make, change, etc.?

I would appreciate any info (mail to me) on how to do this.
Thanks.

Chad

> No, copyright law - or lack thereof - isn't why software gets written.
> It gets written because people need it, or because they want it. All
> the copyright laws really do is restrict the distribution of the
> software once it gets written.

To which I say "Amen!". However, you missed a very important corollary
which has to be considered. And this explains why there is expensive
software. You see, if you were not a programmer/hacker such as myself
and looked at the *vast* majority of the 'free' software available for
say the amiga or UNIX(r) or CP/M even, you would probably notice that
there wasn't a whole lot of what you could use. Sure there are a couple
of things that stand out, but for the most part everything is com programs,
or editors, or languages, or other things that make a programmers life
easier. Thats because we all write this stuff for our own benefit and
enjoyment and are not worried about making money on it.

But how about those programs that the non programmers want and are not
much fun to write? How about a COBOL compilers, or a General Ledger package?
Or how about diagnostics, or just plain old documentation? If you are
like me the only thing that keeps you working on something like that is
either you are learning something, or you get paid. And the person who
pays you may be out a significant sum of money. They naturally want to
recover those costs and thus find similar individuals with the same
requirements and say "Gee, you could pay a programmer $X to write this
for you, or you can pay me $Y (where Y << X) for a copy of this one that
I had written." After n copies are sold, loss turns to profit. And because
we programmers is smart, :-) we often include a little clause in the
contract that says "If you sell lots of these, then we want a piece of
the action amounting to Z% of the gross sales." And I suppose capitalism
is born. By the same token, using this information, one can estimate the
value of a package using the formula :

$$\text{Value} = \frac{(\text{Difficulty})}{(\text{Amount of Fun to write})}$$

Meaning that even very difficult programs (like a compiler) can be worth
less than say a General Ledger because the Fun to write term balances the
level of difficulty.

But one of the nice things the PC has done, is to bring a lot of non-programmers into the computer using fold. And these users need something unique (like a program to calculate the amount of flour to use in any size loaf of bread) and write little hacks to accomplish this, and then send them out to the airwaves. So the diversity, although not necessarily the quality of the available free software goes up.

If PARK tries to reopen the desktop, what then is the difference between PARK and SHIP that is supplied by Atari? On my SH204 I found that SHIP seemed to struggle trying to reopen the desktop, but PARK seems to lock everything up with no apparent struggle.
Am I really doing something wrong? Why doesn't PARK or some similar program just hang in an infinite loop until I turn the machine off? Why doesn't the head lock mechanism disable the head drive motor so that the software can try to reopen the desktop all it wants without harm to the hardware?

>(4BSD).

It was written by a couble of very smart people in a research lab many years ago. It was shared at nearly no cost to Universities for many years. But it was always property of a private company and today is one of their major products.

Where in the world did you get the idea that BSD Unix is free? UCB, in effect, gives away their modifications to Unix, but only to those with a source license from AT&T. For other than Universities, that costs big money. If you don't have a source license, you can buy a legal binary of BSD Unix for thousands of dollars. (10 or 12 I think).

>
>Editors - two of the four I use come gratis with the above OS. The

Nothing came gratis with the OS. They are simply part of the package. You seem to imply that since they weren't priced individually that they are somehow public domain. GNU emacs and microemacs are public domain (essentially), but not ed and ex (unless you are talking about different ones than I am).

>
>Languages - one comes gratis with the above OS; one I had to pay for;
>two were free for the asking (C on 4BSD & a PC, CScheme & T).

Again, nothing comes gratis with the OS, its just part of the package. (Oh, with one exception, I guess the "user contributed" stuff than comes with the BSD tapes could be called gratis, but C certainly isn't part of that.) C in BSD is most certainly not *free*. It is based on AT&T code. If you are running Unix, using the AT&T C compiler and you didn't pay somebody for it, then you've got a bogus system. I grant, that it might look free, if you buy a Unix box that has Unix bundled

with it; but its certainly part of the cost and your vendor sends a
check to AT&T for each one sold. (Note that some vendors have written
their own C compiler for use on their Unix boxes, instead of using the
AT&T code, eg. Masscomp did this, but I assure you they don't consider
it "shareware".)

Most software is written, because its a legitimate way to earn a living
and to build a business. Sun didn't write Suntools to be nice guys;
they wrote it to make the systems they sell more attractive.
Try taking their code, and making minor changes for your AT and see what
they do. They don't charge extra for it when you buy a Sun, but they
don't call it free, and that doesn't make it up for grabs.

I almost flamed this, then I almost ignored it. But then I realized,
that for about 90% or more of all shareware that I have seen, I agree.
(ok, maybe I don't called it immoral and disgusting, but the idea is
there.)

The difference in my view is that I feel a distiction must be made
between different 'classes', if you will, of shareware. There are the
neat screen hacks, directory commands with a twist, little foo-foo
utilities that we can all live quite nicely without. The quickest way
to piss my off is to give me a neat little utility, something that
does something really nifty, or maybe does some little thing just the
way I wanted; and then tell me "If you find this program useful, please
send $10 to..." Usually these programs have a guilt message when you
run them. If I get disgusted enough, it's enough reason to toss the
particular offender in the bit bucket.

On the other hand, there is a more elite class of shareware; programs
that are in fact of commercial quality (yes I know that's ambiguous) or
are better than commercial programs that do the same, or are not as good
as program X, but do cost $25 instead of $200. These programs are

legitimate shareware in my opinion, and I try to honor the authors request and either pay for the program or don't use it. Usually paying for these programs is actually to your benefit, in the form of upgrades, documentation, support, etc. These include (in my opinion) Procomm, (at least earlier; is it commercial now?) PC-Write/file/calc/etc., Chiwrite, or for the Amiga, Uedit, Mcad, Dirmaster, and lots of others.

Maybe we should coin a new term for the former class...GreedWare? B-)

> In article <174@piring.cwi.nl jack@cwi.nl (Jack Jansen) writes:

> Ok, I'll come up with something original. The problem is capitalism.

Well, no, not really. People own their labor and their time, and within reason they can use these assets however they wish, whether it's writing software, growing wheat, or just goofing off. This is not a 'problem' but a kind of basic human right. You might just as well say that the 'problem' is the failure of software to just magically appear from nowhere without anyone having to do any work.

People want money back in return for their efforts, and aren't satisfied with fame or esteem or whatever else. Now, that is reasonable if you make 'hardware': a knife is a knife even if you don't want to share it. But, it doesn't work for ideas. If I write a beautiful song, but I don't sing it (or, preferrably, let others sing it) in public, I might as well not have written it in the first place. It's value is in publication. The same is true for books, philosophies, ideas and (to a certain extent) software.

There is little difference between hardware and software as far as their reason for existence is concerned. A knife is simply a tool; there is not much you can do with it unless you have something you want to slice up. Likewise, a word processor does you no good unless you have something to write. Your word processor might be so well designed that it reminds you of a beautiful, harmonious song, but its quality doesn't alter the fact that it is simply a word processor. A finely crafted and perfectly balanced piece of kitchen cutlery is still a knife.

Your conclusion that something's publication is necessary for it to be valuable is just simply wrong. A diamond is valuable even before it is mined; a house can be a warm and stimulating environment even if no one but the owners ever enter it. Suppose that I write a very specialized program and sell it to a few specific businesses whose needs it fits completely. Is it then valueless?

Excuse me, but I always thought the idea of shareware was, "Here's a PD program I wrote, feel free to us it. But IF YOU CAN, send a donation. I don't demand that you do, but it would make me feel better."

Whether you're a scumbag for getting shareware without sending a donation or not doesn't seem to be the question. Rather, what IS the nature of shareware? All the shareware software I've seen on the Ataris (PICSWITCH 0.7 on the ST and GAUNTLET on the 8-bits come to mind) seem to impose the "Money is nice, but not demanded" idea...

Now THERE'S a theory! It rather struck me as odd that Infocom would "stop/lower their Atari support", especially since it IS (as you said it) formatting text. I've completely forgotten about the Activison link there.

But then, what COULD have happened between Activision and Atari? I doubt the "former Atari programmers" would be angry at the NEW Atari, since Jack Tramiel wasn't even around at the time. Must be some kind of behind-the-drapes deal that got blown, maybe?

This would also explain why Activision's first ST program, FILM DIRECTOR, still hasn't been released (it was mentioned in an Activision newsletter from last October, and I'm still waiting!)...Hmmm...

--R.J.
B-)

P.S. I know it's been officially denied, but I *STILL* like to believe there's some hanky-panky between Electronic Arts and Commodore to stop Atari support... (I'm sorry, but Trip Hawkin's interview in ANALOG a few months back didn't hold water with me)

<today is one of their major products.

That doesn't negate that it was illegel for that company to sell the
OS when it was written. They "shared it at nearly no cost" because the
judge that decided they could sell "refuse of internal work" also
ruled they couldn't make a profit on it. It wasn't until the company
was dismembered that it could be treated as a legit product.

<>Further
<>enhancement was done by a seperate group that has been giving it away
<>for the cost of time & materials, and may be required to do so by law
<>(4BSD).
<
<Where in the world did you get the idea that BSD Unix is free? UCB,
<in effect, gives away their modifications to Unix, but only to those
<with a source license from AT&T.

Sorry - ambigious antecedents on "it". I was referring to those
enhancements, modulo licenses on the original source. But there are
large pieces of code that *aren't* covered by any license other than
the Berkeley ones. Work is underway to sort out what can and can't be
given away - and parts of that OS are already in the "can be given
away" state.

<Nothing came gratis with the OS.

True - there are people obnoxious enough to seperate out the C
compiler & editors. Most of them seem to be failing (or have already
failed) in the computer market.

AT&T doesn't charge extra for giving someone the editor with Unix -
last time I looked, the only thing you had to give someone when you
sold them Unix was /etc/init & /unix. No shell required. Since then,
they've started doing "validations." I would be surprised if at least
one shell weren't required, and wouldn't be surprised if an editor (or
two) weren't required. Whether the result is "gratis with the OS" or
"part of the package" is word games.

<You seem to imply that since they weren't priced individually that they
<are somehow public domain. GNU emacs and microemacs are public domain
<(essentially), but not ed and ex (unless you are talking about different

<ones than I am).

No, you implied it. I said they came at no extra charge ("gratis")
with the OS. You have to have a license for the OS. That license
covers all the things I mentioned. On the other hand, microGNUemacs is
mostly public domain - some of the machine-specific files have
copyrights still held by their authers. I don't know about microemacs.
GNU is *not* public domain, and the copyrights are held very tightly
by the FSF. Just to prevent people from selling it for money.

<C in BSD is most certainly not *free*.

C in BSD is free from BSD, once you've dealt with the legalities of
getting the rest of the system - "gratis with the OS." Of course, the
legalities probably won't involve any large telecom companies for the
next release, as CSRG is working on switching from PCC to the GNU C
compiler.

<If you are running Unix, using the AT&T C compiler and you
<didn't pay somebody for it, then you've got a bogus system. I grant,
<that it might look free, if you buy a Unix box that has Unix bundled
<with it; but its certainly part of the cost and your vendor sends a
<check to AT&T for each one sold.

No, the vendor does *not* send a check to AT&T for each C compiler
sold. Not unless they've radically changed their licensing since I
last dealt with them. The vendor sends a check for each Unix system
sold, and can't give (or sell) a C compiler to anyone that didn't buy
a Unix from them.

<Most software is written, because its a legitimate way to earn a living
<and to build a business. Sun didn't write Suntools to be nice guys;
<they wrote it to make the systems they sell more attractive.
<Try taking their code, and making minor changes for your AT and see what
<they do. They don't charge extra for it when you buy a Sun, but they
<don't call it free, and that doesn't make it up for grabs.

Suntools makes Suns more attractive? Giggle. What a laugh. And I don't
deal with obsolete hardware - unless it's noticably faster than
anything else I can get my hands on. Things using intel processors
prior to the '386 are always in the first category, and never in the
second.

I agree, *some* sotware is written specifically to be sold. Probably
even most (but not all) of the software being sold. But most software?
I doubt it. I claim that most software is written because it was
needed to get some job done. What becomes of it after that depends on
lots of things. I suspect that *most* software is written by the
government, and people doing work for the government. Most of that is
public domain modulo licenses that cover whatever was started with.

For instance, I worked on a C compiler for an obscure machine you
probably never heard of. You can have the front end (if you can find a

copy somewhere) for nothing, *if* you have a license for v7 Unix. The back end doesn't have that restriction - you're welcome to a back end that swallows pcc-produced trees and generates QM/C code if you want it. You can even get the QM/C simulator I wrote - either the one in C, or the one in QM/1 nanocode. You just have to find someone who's still got a copy.

1302. Absoft Fortran...

Newsgroup: comp.sys.atari.st
Date: 1988-01-23 16:36:00 UTC
From: FXDDR@ALASKA.BITNET
Message-ID: <8801232137.AA06104@ucbvax.Berkeley.EDU>
Source record: 254902

Thanks to the leads provided by people here, I was able to make contact with Absoft. Turns out there are two reasons why AC/Fortran is a little hard to find: (1) Absoft moved recently, and (2) apparently sales to ST users have been underwhelming. Anyhow, one distributor is Computer Creations, PO Box 493, Dayton, Ohio, 45459 (advertisements in STart). It is also available from Absoft directly at their current address:
Absoft
2781 Bond Street
Auburn Hills, Michigan 48057
Ph (313) 853-0050
They want $199 for it...Computer Creations wants $129.
The flyer they sent is annoyingly amigoid. At the top it says "ANSI FORTRAN 77 Compiler with Debugger for Amiga" and down in the description it says "AC/FORTRAN is the standard...for MC68000 based personal computers (Macintosh, Amiga, Hewlett-Packard Integral PC, etc)." The only clue that they support the ST is the statement "It...includes several Atari ST productivity tools such as...."
No wonder the ST sales are slow...the casual reader wouldn't even notice that an ST version is available!
Oh well, the marketing folks can't all be geniuses.

Thanks for the assistance,
Don Rice
FXDDR@ALASKA
PS: Thanks Ravi, I think you are the only one I couldn't get a reply to.

1303. Re: Software (and other kinds of) copying

Newsgroup: comp.sys.atari.st

I think one of the main problems of copying software is the attitude of the
software companies. If they implemented a 30 day money back system so proper
evaluation of software could be made, then I think sales would fall (if it is
a crappy piece of software) or the number of legit sales would increase (it it
is good and usefull). Take for example microsoft C, or Wordperfect for the atari - both are
full of bugs, both don't have return policies - but how do you
find out that the software is bad without spending $400 on it?
Wordprocessors are another point - what to buy - microsoft word or wordperfect.
No matter how many reviews you read it boils down to personal choice - again
you have to buy both packages with no return to see which one you prefer.
With some packages you can get limited demo disks but they still don't model
a real application.
In Canada it is now a criminal offence to copy software - I think the law
should be ammended to allow proper evaluation of software with a reasonable
return period.
Enough said - things will never change anyway ...

You're wrong. One of my vices is reading the advice columns in the local rag, including the BBB & Legal Questions columns as well as the national ones. Over the past 10 years, the problem of getting something that you never ordered has been dealt with over and over again, and the answer is this:

If you recieve something in the mail, and you didn't order it,
congratulations. You are now the proud owner of a free gift!
There is no obligation to send it back, or pay for it...
although you may have an obligation to contact the vender
and notify him that you did not order it, especially
for things like magazine subscriptions. See the appropriate
parts of the U.S. postal codes....

In general, the law works much like Mike mentioed... if it's free, someone can't come back and tell you later that it's NOT free.

Oh sure, real leach, huh? Mike Meyer has probably written more public domain software in a year than you've written in your entire life. He doesn't just stand in line to use other's software... he contributes, too.

A friend here in Lafayette has a shareware program out that prints mailing labels in various fonts, with Print Shop graphics on them. He doesn't make random exhortations about "software leeches" or anything like that (for one

thing, he's a gentleman, in all senses of the word, and doesn't do things of that sort). He doesn't ask for tons of money -- he already has a full-time job, and besides, the friggin' program prints mailing labels, it don't do dishes or anything else. Mostly, it's just a way for people to get the latest version for a donation of $10 or equivalent (for example, someone in Australia with access to a printing press sent him 500 beautiful diskette labels, gold-color, with the program's logo on them...). And, incidently, an excuse to get lots of mail from around the world (he probably spends more on stamps than he gets in donations :-}. Whenever I see something that asks for tons of money to use, I mostly chortle and toss it across the room into a growing pile of disks that one day I'll have to scavenge... there's very, very few things that I use often enough to pay for (like that mailing label program, for example, which I used so often that I finally sent the guy $15 -- which, now that I think of it, is about the only shareware that I've EVER used, since my main use for my computer is software development, and most development tools either cost money or are a quick "C" hack).

>
Shareware writers drop their software into the PD distribution channels in order to avoid the expense of commercial advertising, thus enabling them to ask for smaller fees, saving themselves *and* the satisfied users some money (unsatisfied users need not pay). Shareware software is NOT PD software. Ideally, a shareware writer will spend a good deal of his/her time making the software of commercial quality.

I do not believe shareware marketing is an attempt to make a "quick buck". A great deal of time and energy may go into a shareware product. Although all of this sounds good in theory, I do not believe it is working. Some form of quality control may help.

As the responses to a related discussion in comp.sources.d showed, many of the high quality PD programs that are available are free because the authors were prevented from marketing their work due to contractual restrictions.

> that I've missed.

"Uneforceable" without a police state, yes. How enforceable a law is,
is a function of what abuses people are willing to tolerate. No one would
accept no-knock warrants and warrantless searches to stop software piracy.
(Though most people would tolerate it stop drug dealers or terrorists.)

The enforceability of a law says nothing about the morality of the action
that law prohibits. (Of course, talking about right and wrong with the
well educated crowd on USENET is a complete waste of time).
>
> When producers of the software start seeing adding something that
> makes the product inferior as a *good* thing, it's time for a reality

Maybe not a good thing -- maybe something they need to put in, since
by your claim, stopping software piracy through law is impractical.

I would prefer copy protection go away. But if the only alternative to
use of the legal system is copy protection, I think we are going to see
it around on high-end packages for a long time. (It of course being
impossible to get software users to stop stealing the stuff).

> For computer programs, we have software protection in various flavors.

Nothing is wrong with it -- there's just too many people out there who
believe that stealing intellectual property is a right. Consequently,
you can expect these sort of damn nuisances.

<neat screen hacks, [...]
<On the other hand, there is a more elite class of shareware; programs
<that are in fact of commercial quality (yes I know that's ambiguous) or

There are to many levels to break it down into just three categories.
I think you need at least three independent quantities:

1) usefullness: ranging from cute screen hacks (hi Leo) to things you
use every time you turn the system on.

2) quality: Mostly, how bug-free & well documented is it.

3) greed: ranging from an obnoxious message that appears everytime you
use the program, to no request for money whatsoever.

I expect you can find programs in any of the eight corners.

But there are *still* oddball cases that don't fit. There's a Logo
floating around for the Amiga. It behaves in a manner I'd consider
most offensive: you have to look at a message everytime it comes up
asking you to send money. It's a solid program, and mimics Apple Logo
(so you have to get the documentation from elsewhere).

However, the message doesn't say "Send me $'s", it says "If you
haven't made a large contribution to the public domain, could you send
money to <non-profit organization for teaching third-world children to
read>".

I applauded, even as much as I detest most programs with such
behavior. I called the author, chatted with him about it (found out
that the copy I had shouldn't have been release, as it was still in
beta test), and congratulated him on that.

You see, though the message behaves in an offensive manner, it captures
the hacker ethic - give your software away for the good of the
community. He just used the shareware hack to urge those who hadn't
contributed in the same way to help in a different way.

Greedware? Clearly not. Shareware? Yes, in the true sense of the word.
In the normal sense? I dunno...

Your available software just got very limited if you aren't going to use
GEM/TOS, especially graphics. Note: I don't really use the mouse interface
myself since it is so crappy compared to the Mac. I have a home brew UNIX ksh
like environment.

> OS-9/68000 is a TRUE/FAST/REAL multitasking/multiuser system...
add ^/REALTIME here
> Unix(TM etc.) is almost as good as OS-9....

This may have been humor, but when you are talking about a small machine with
no MMU OS/9 is FAR superior to UNIX except in volumn of software. Although
the available software that would run under UNIX on anything but a 2 Meg
memory and 20 Meg hard disk ST is rather limited....
Maybe a shared segment version with the kernel and standard libraries stuck
out on the ROM port? Hum, that might work.
Idris has a bad reputation on the PC. But, what should we expect? CP/M 68K
and GEM have bad reputations too. That's why Atari gets them cheap enough
for their tastes.

>Moshe used do any good on the atari disk?
>

I believe what Jim has come up against here is the "soon to be as
famous as the 40 folder limit" bug in the file creation system.
It seems that the programmer who wrote the GEMDOS routine to find
the first free allocation block on a device was as clueless as the guy who
designed the directory system.
This brings up an interesting idea. Gemdos is certainly a usable
system, but...
We have a limited number of folders (static).
My hard drive creates new files slower than my floppy.
The OS doesn't do any sector level buffering.
These features remind me painfully of my experiences with TRSDOS on a
1977 trs-80!
Gemdos calls are based on traps. These are notable in that they are
VERY easy to intercept. How 'bout patching the OS to take care of a few of
these bugs? eh? Apple does it with the Macintosh, so there is no reason it
can't be done on the ST. I realise that the desktop being merely an application
is harder to patch, but GEMDOS is quite an easy patching target
So, how 'bout it Atari? How 'bout releasing patches as they are written
for insertion into our AUTO folders, instead of making us wait for new ROMs?

>Thanks.
>
>Chad
>
>BITNET: CHAD@BYUVAX

I just completed another upgrade of the 520STfm machine. This last
machine was a revision D mother board.

The only things that you need are
16) 256 by 1 Drams (200 ns (150 ns is better))
16) Sockets for these (if you want to socket them)
16) .22Uf 25wv Ceramic Caps.

I use the easy mans means to make the mod in short order but you may
not have the tools that I use. I would suggest however, that you find someone
who may, and try and borrow it. Makes life alot easier than the solderWick
method that i'v heard others use. By this I mean, try and get a small PC board
drill. I used a Wahl Iso*Tip quick charge pen with a drill attachment. The
size drill I used was a .0330 Dia bit. Then I just proceded to drill the
closed holes open. This way I left some of the solder still there and and
did not run the chance of overheating the PC Board foils so as to have them
lift up. (Bummer when they do that)

Insert the sockets and solder in, then insert the Caps and solder
in, then finally pop the Drams in the sockets. Thats about all there is to it.
I used a 700 degree isolated, temprature controlled soldering station, but
the main drift here is not to use any more heat than needed.

Assemble the machine, less the rf sheild (until you know it's working
correctly) and boot up. Either run one of the Ram Check programs OR just a
simple P/D Ramdisk program, and create a 600K ramdisk. If you got all the
solder connections correct, you have it made. If you cannot create the
ramdisk, then check to make sure that the connectoins are all there. The
machine will still boot (unless you really have something screwed up) as the

first bank you never touched.

I payed $89.00 for 16 NEC Drams, $24.00 for the sockets, and
$4.?? for the caps. Took 1 hour 50 minutes to complete the job, though if
your not as experienced as I, take your time. One mistake, and you could be
out a whole machine!

-rich.....

Thank you to the bzillions of people who referred me to
STARTGEM.PRG. For those who want it but missed
it's most recent posting, it's also available on score.stanford.edu.

I wound up putting STARTGEM.PRG in A:\AUTO\
and UNITERM.* in A:\, with the program name string in STARTGEM.PRG
changed to "A:\UNITERM.PRG".

-- Paul

P.S. I can do without the "jeez, didn't you get it the *last* time
it came by?" comments...it all depends on when someone started
reading the newsgroup, doesn't it. If your site keeps every
netnoise message ever sent, good for you, but poor public schools
like Berkeley don't have that much disk space.

Perhaps a biweekly (monthly?) message should be posted which
describes the "usual" issues:
FOLDRXXX.PRG, STARTGEM.PRG, COMMAND.PRG (to start GULAM) ...
what ftp/LISTSERV servers are available and how to use them
uud, uue, arc, shar ...
the time since the last comp.{binaries, sources}.atari.st
posting :-)
etc.
Comments? Volunteers?

One bit of nastiness to watch out for is the keyword "entry", which is or is not in ANSI C, depending on which draft you look at. In any case, the error message is "declarator syntax", not very helpful, and the Lexicon doesn't mention it except in a rather obscure place (thanx to Sandra Loosemore for finding the reference!). This is version 2.0; dunno if it's been fixed.

Other than that, MWC is good, especially considering the limitations of the brain-dead operating system that looks like it was designed over the weekend, in between hot-tub sessions, by folks who were proud of their lack of education...

>
I would assume that Uniterm looks for the .inf file in the the
"current directory" (cwd for unix folks). When using GEMSTART the current
directory is either 1 of two things.
1. if you have any windows open according to desktop.inf, then
cwd is the top most window.
2. if you have no windows open according to desktop.inf, then
cwd is the root directory of the boot device.
Try making up a disk with no windows open, and sticking uniterm
and its files at the root. This should work fastest.

We're talking "here's the chips, now get them installed". With all the various boards out there, it seems that there was no better solution.

Pricing is not yet finalized, but should be around $120.

Seems reasonable. Now two little questions Neal. One, does that include the roms? I don't really mind if they don't but I don't want to order these things and not see rom chips because I should have bought some. Two, could I have a rough time estimate as to when I could get these neat little chips. Say somethine accurate to a one month period or at least a greatest lower bound. You said real soon now but well I equate that with "let's have lunch" or "we can still be friends".

Source record: 254922

Hello Atari lovers,

This is a reply on the problems mentioned in a recent digest about how to
startup UniTerm with GEMSTART, without bombs.

I did also had the same problems, four bombs and everything dies.
Here is the solution:

-1- Put the program GEMSTART.PRG as the last program into the AUTO-folder on
the bootdisk.

-2- Change with a disklook program (e.g. DISKDOC.PRG) the sentence
"Autostart of A:\UNITERM" into "Autostart of $PATH$UNITERM.PRG"
in the file GEMSTART.PRG and save the modified file in the AUTO-folder.

NOTE: $PATH$ stands for the full pathname for the location of
UNITERM.PRG (e.g. B:\UNITERM2.0A\)

-3- Create a desktop with the file window opened inwich the program
UNITERM.PRG plus aux. files are located.

-4- Save the desktop on the bootdisk and reset your system.

-5- UniTerm should now autostart without any problem.

I hope that the guy who had this problem will be out of trouble now.

Greetings,

Victor Ronnen

> those laws have helped to ensure that the distribution remains free and
> easily accessible to everyone (without random people making money off it).

Copyright laws don't restrict the distribution of software -
they merely allow the author to decide if he/she will impose any
restrictions on the distribution so as to protect the investment made in
developing the software. It's interesting to me that the same copyright
laws are invoked (and rightfully so) by the shareware developer who wants to
protect his/her good name as by the commercial software developer who
wants to protect a merely :-) economic investment.

I am amazed at how much discussion the topic of copying
still generates though. It's like a discussion of shop-lifting with some
arguing that it's okay because the store is charging too much and others
saying that it's okay because the house detective is asleep and doesn't
care anyway. It still comes down to theft (yes, Virginia, theft is still
wrong whether or not you get caught....)

I don't have a problem with copy protected programs either
because I don't buy them and I encourage others to do the same.
And obviously a lot more people feel the same since the use of copy
protection is on the decline. It's *amazing* how that evil capitalist
market-place :-) responds to the desires of the buyer rather than the seller
when there's enough competition.

Are the any people from or near PELL (The home of STadel) on the net? If so, some people here in Ottawa are just starting to experiment with STadel V3.0c. We would like to get a copy of any news updates since 'citanews 687', a copy of the alternate helpfiles mentioned in one of the citanews files, and a copy of any utilities that have been developed (excluding: Clog; Lexpand, Logedit; Popular; and Citsh). We have a copy of Expand, with no .docs and have the .DOCs for but do not have: Recoverl; ctdlchng; and Citar. If you can work out a path from the addresses below, I'll send copies of any goodies that you can send to the archives at CANADA01.

Question: What are people using networking for? Clearly, international networking is wonderful! But in a typical local calling area of about 1/2 a million people, what does networking do that 'standard' BBSs do not? *NOTE* Please, I am not trying to be provocative. I would really like to know what is being done, not start a flame war. I just have not thought of an application in a local area.

Thank you in advance. /JT

<"Uneforceable" without a police state, yes. How enforceable a law is,
<is a function of what abuses people are willing to tolerate. No one would
<accept no-knock warrants and warrantless searches to stop software piracy.
<(Though most people would tolerate it stop drug dealers or terrorists.)

I'm not willing to grant that a police state can enforce a law against
software piracy - except by going to the extreme of making it illegal
to own a computer. You should check out how the Polish resistance
movement is making use of computers.

<The enforceability of a law says nothing about the morality of the action
<that law prohibits. (Of course, talking about right and wrong with the
<well educated crowd on USENET is a complete waste of time).

Likewise, the existence of a law says nothing about the morality of the
action that law prohibits, either.

<Nothing is wrong with [copy protection] -- there's just too many people
<out there who believe that stealing intellectual property is a right.
<Consequently, you can expect these sort of damn nuisances.

No, there is something wrong with it. The law is set up to try and
turn an oxymoron (intellectual property) into a reality. As usual,
when a law tries to change reality, it gets ignored. Expecting
anything else is silly.

BTW - I *don't* condone stealing software. While it's not immoral, it
is unfair and dishonest. You should play by the rules until you
manage to get them changed.

>does allow the lockout of the menu bar, which may be the reason for the
>not so clean break upon exit. Nite I can understand, to blank the screen
>but another screen saver utl may solve the other problem your experiencing.

I keep moustrap resident because I like the menu bar locked all the time, and not just when I'm in Word Perfect. (Once you get used to moustrap, it's impossible to do anything without it. Menus start dropping all over the place; and *imagine* having to manually move the mouse up to the menu bar! Uugh.) Anyway, your first thought was mine too. Even when I boot WP cold with *no* accessories or utilities resident, it doesn't clean up after itself properly, and subsequent applications (e.g., Uniterm 2.0a 003; try it and see) lock up or misbehave if I don't reboot.
Of course, nite and/or moustrap might be responsible in part for some of the other bugs I've run into. E.g., the WP manual states that you can record macros using either the menu bar commands or keyboard equivalents. I've found that the mouse commands work only sporadically or not at all when recording macros, and it's just possible that this behaviour is due to having moustrap resident (though I doubt it, since the macro presumably records just the commands, and not the actual mouse movements). No big deal: just make sure to use keyboard commands while recording macros. Given the ease with which one can work around this and similar bugs, a wholesale application of Mill's methods in a last-ditch attempt to confirm that WP gets along well enough with my resident utilities just doesn't seem worth the trouble.

> Key click problem, well I can't say that I have encountered that
>either, but then I don't have the volume up, as it slows my typing down ;~}.
>Unless your talking about something different than I am interpreting.

If I'm not mistaken, the key-click problem is really due to a TOS bug, which the authors of WP for the ST apparently weren't familiar with. If you've been running for a while, under certain conditions (not sure exactly what they are, though I seem to encounter the problem when I'm using the mouse a lot) your machine will start clicking away as if you were holding down a key. (Assuming that you have the volume turned up, of course. Just how fast do you type, anyway, Rich? :-)) As a side effect the Repeat dialogue often pops up in the middle of your screen, since the bug in question makes TOS think that you're trying to choke it with escape characters, and WP uses the escape key to call the Repeat sequence. Again, it's a trivial problem -- just hit <UNDO> and carry on with what you were doing. (I think Moshe Braner ran into a similar difficulty with early versions of more.ttp; perhaps he could comment?)

For anyone considering buying WP, I'd like to emphasize once again that even *with* the bugs in the current version, it's eminently usable. I had the luxury of being able to borrow a copy of WP from the English Dept. here last fall. I gave it a fairly solid workout for a couple of months, so I had a pretty good idea of what bugs and limitations I could expect to encounter, before I purchased my own copy. (The educational price in Canada, BTW, is $160). If you need the power (I especially like the recursive macros, and the superb merge facility), WP is indeed worth every penny.

Jim's article <2697@dadla.TEK.COM> is absolutely correct. Why *is* there no CHKDSK.TTP or whatever? Lord knows there are enough known bugs in the filesystem that a correction-and-defragmenting utility ought to be standard issue with any SH product. I have worked around this by doing entire dumps (via TURTLE) of the SH204 to many, many floppies and then reformatting, building new partitions, testing, and restoring. This is tedious at best and error-prone & dangerous at worst. I do it Sunday afternoons (like today).

Jim is also right about relative filesystem performance. Any ibm-clone XT-class machine in the building can beat my ST/SH in general filecopy performance. Good grief, 1024 Kbytes of RAM to play with and they don't even cache the FATs much less the directories, or attempt read-ahead or any of the other tricks that (even with the brain-damaged toy MSDOS filesystem) could easily be done to improve performace. The hardware is certainly quick enough. As an example, when I run my machine under the Magic Sac mac-emulation system, I notice a considerable improvement; the hard disk performance approachs TOS ramdisk speeds.

My interim solution has been to logically separate my files into two groups; files which are essentially static and read-only (executables and resource files, libraries, standard #include stuff, documentation and the like) and files which are mutable and/or ephemeral (source, mail, databases, pictures, any work in progress) and assign them to different partitions.

The mostly-read-only partition is loaded in the order of expected usage frequency (i.e., \bin first, then \include and \lib, then \doc and so on) and can be allowed to become moderately full (say 75%). The read-write partition holds \src and whatever else you have, and shouldn't get more than 30% to 50% full. In either case, small partitions are a speed win. I always go with 4 x 5 megs for simplicity.

The final thing is to assign a RAM partition for really ephemeral stuff, like compiler temporaries, .obj's, and suchlike objects.

Even with all this planning, the XT's still beat my ST. Are you listening, Neil? Your people are crying out for help ;-).

BTW, here's my bench: compile microemacs 3.9e from scratch. times:

17 mins 32 secs with c:\{bin,lib,include}, d:\src, m:\tmp
13 mins 25 secs with everything on m:\ (ramdisk).

(MWC 2.1.7, stock 1040STf or ST-4, stock SH204, in mono mode, no acc's; in both cases, the command was 'make clean; time make')

Who's got PC/XT times for this? It's a good test from my
perspective; lots of compute, lots of reading, a fair bit of writing.
And its the kind of job load that I often offer this machine.

> At least the 68000 computes faster...:->

But this is getting to be cold comfort :-< !

I'm not sure if I understand this. Does this mean that atari will provide a hybrid in dip form which contains the blitter and 68000 to plug in in place of the existing 68000? I can't help noticing that the 68000 on both of my 520s is soldered in. I would attempt its replacement but how many others would? Or on the other hand, does this mean all we get a blitter with no home at all? I certainly don't have any place to put it on my mother board.

To: INFO-ATARI16 at SCORE.STANFORD

Please don't post anything without asking me first! (Uncoordinated posting tends just to use up net bandwidth) I mainly just want to make sure the current version has really settled before posting (just to show how much can change in 3 weeks: the version which is accessible from various servers should be 2.0a 006, the version I'm using to write this with is 2.0a 012 which has a few minor annoyances fixed, plus some additional features).

Even if I don't really have to justify myself, just a few words on why I decided to move the documentation to LaTeX:

- It's a lot easier to maintain a table of contents, index etc.
- The resulting document actually looks a lot better (particulary in respect to the amount of work I put into it, the old version (1st Word) was rather disappointing).
- There are still quite a lot of people who can print DVI files and the best way to get a copy of the doc's (in my opinion) would be to make a double sided copy (it's formatted for that!) from somebody who's printed it (saves 50% of the paper etc.).
- At the time I made the decision I (mistakenly) thought that it shouldn't be all to hard to produce a ASCII only copy. But after a lot of hacking up DVITYPE on my ST (no problem to port with CCD/OSS Pascal), I've more or less given it up (if the folks that have produced a human readable copy would be so nice to send it to me, I'll update to reflect the changes since the time the DVI file was created).

Anyway, in not so a long time you should be seeing UniTerm on the binaries group.

Simon

To: INFO-ATARI16 at SCORE.STANFORD

I must admit I was wrong: the Atari PC-1 does exist, despite me claiming
that it was just vaporware. In fact I spent an hour or so playing around
with one last week (BTW the Atari Laser has been available here for about
two months (on the other hand I don't know anybody here who has actually
seen a Mega ST2, the only thing they sell here is the ST4)).

What I like about the Atari PC:
- good color graphics (which just rubs in the point that Atari
hasn't improved the graphics quality of the ST series over
the last 3 years)
- comes with mouse and bundled software (GEM Paint & Write)
- has enough documentation (a rough guess, more than 500 pages
which is naturally another sore point with ST owners, when
I got my ST the only thing I got was 80 pages of mostly useless
docs, there wasn't even a Basic manual in those days) for non-
programming purposes.
- is very cheap (costs something like 4 times the price of PC-Ditto)
- quite a good keyboard (better than the one on a ST4, which costs
nearly 4000.-SFr. compared to the 1000.-SFr. fot the PC-1)
- has a very nice monchrome monitor, which compares very nicely
to the horrible SM125 that is being sold with the ST's now (I'll
never give my SM124 away!)

What I don't like:

- slow (what do you expect from a 8088)
- pretty useless, the amount of things you can do with a slotless,
single 360kB drive, 512kB machine are VERY limited (one thing
you can do is run Turbo Pascal 3.0, I'don't know if you can get
a useful TP 4.0 configuration on one floppy), in fact using
the bundled software is a real pain since you have to swap disks
to return to GEM Desktop after you've exited an application (and
to start the application aswell).

>should stick with the 1040ST (and who would EVER want 2meg :-)). I can
>follow his thinking, but I'm not sure whether it is based on true
>experience or just hypothesis.

I suspect that this dealer just has a higher margin on the 1040 :-)
The Mega is in almost every respect the better ST. It is so similar
to the 1040 et al that there are virtually no compatibility problems
(programs which use undocumented system variables break).
But you get a much better keyboard, more memory and a nicer case :-)
And there is the battery-backed-up clock, the blitter support,
the coprocessor support etc.
One thing that I don't like too much about the Mega is the fan.
Though the one in front of me is rather quiet, it's still a noise
that does not belong in an office. I know that almost no PC comes
without one nowadays, but I don't like it...
Another thing (I hope Atari will fix it soon) is the weak
construction of the keyboard cable plug. It looks like it is
very easy to break. I did not try it yet...

'nuff said. Go for the Mega !

It depends on the concept you are trying to prove. The universal
(non)ownership of all software? Not hardly. That one man's success
validates his philosophy? Wrong again. That P.T. Barnum was right?
Probably.

>unfathomable.
MichTron sells a program called "TuneUp!", which I have purchased, which allows reordering and consistancy checking of hard-disk structures. It is not perfect -- It is not robust when the hard drive is almost full and you have large files, so back up your files before doing a reorder on a nearly full drive and it does not supply a method for fixing problems that the checkdisk feature reports -- but it is the first program I've come across that offers these features. It costs < $50.

>
From conversations I've had with people "in the know" at Atari, the problem here is with the TOS code for handling directory and FAT caching and lookups. Though a rewrite has been underway in-house, the ROMs for the Blitter (the ones in the current Megas) do not contain any of the re-written code because it had not been tested in the timeframe required. Look to Atari to eventually release a version of TOS that will outperform the old versions by quite a bit. The most expensive (time-wise) operation on the ST is opening a new file. On a hard disk with a lot of activity but over 50% free has sometimes taken over six seconds. This is the reason that Mark Williams recommends using a RAMdisk for the temporary files (TMPDIR) and supplies a RAMdisk with their package.

1339. Beware: Munged HD ahead

Newsgroup: comp.sys.atari.st
Date: 1988-01-25 15:48:07 UTC
From: exodus@uop.edu
Message-ID: <966@uop.edu>
Source record: 254938

Just in case this should happen to any fellow HD owners...

Configuration:
-Atari SH204, replaced the Tandem drive with a Micropolis 1304 (a la SUN Corp).
-Runs with the Supra Autoboot program, foldrxxx.prg, Beckemeyer's Hd accelerator.
-Formatted with the Supra Software (and possibly this time with the ICD software... I cannot remember)
Problem:
I ran Supra's partition check software in the 'destroy' mode on Partition 'D' (~13 Megs). Partition 'E' was trashed afterwards.
Diagnosis:
Partition 'D' possibly had an 'orphan' sector at the end which was not part of a clustor. Might be caused by either Supra's or ICD's partitioning software. Supra's Partition check program assumed it _was_ part of a cluster and tested the _next_ sector also... Partition E's logical boot sector. That sector was found to have the Test pattern in it (the ASCII set over and over).
Cure:
Made my own logical boot sector for Drive 'E' ... creating and testing the it as I went. (Re-boot each time you change a boot sector -- only way to get the computer to recognize the new values). DLII and Disk Doctor are essential. DLII for its checking capabilities. Disk Doctor because it will let you edit a partition with a mangled boot sector-- DLII will _not_.
Planning ahead:
Besides the usual backups, keep around a dump of the boot sectors of all of your partitions as well as the physical boot sector of the drive. Otherwise you will have to re-format your drive after recovering as much data as possible from the one messed up partition. It's a good idea anyways. Perform an image backup (i.e. Tom Hudson's Backup Program from STart) every once in a while if your are in the Turtle Camp. The image backup can save your life and takes little time (just more disks).
****
Now, if anybody has any other clues to why this happened to me (or why I am wrong), Please let me know. I spent 5 hours re-constructing the mangled partition to get the recent, un-backed-up, work that was on it. It wasn't fun. Possibly some disk/directory editors that had a mode for fixing disks... DLII bombs if something in the BPB (BIOS Parameter Block) is even slightly wrong. Disk Doctor did some strange things (filled my monochrome screen with static, or something pretty close). [That was a hint, btw. I don't have the time, but someone may have!].

DO NOT LET THIS HAPPEN TO YOU. DO NOT BELIEVE A PROGRAM'S "NON-DESTRUCTIVE" MODE or that it will restrict its actions to a particular area of memory or disk.

Who doesn't have to pay the author of the program at all. You still haven't
come up with a method that incentivizes writing software.

> that plans to sell the hardware! Apple corp. is giving Hypercard away
> (almost) even though it must have taken a staggering amount of work to
> create. Why? To enhance the Mac's usefulness image ---> more HW sales.
> Other options: a tax on blank disks could provide funds for public SW
> writing efforts (a la Berkeley, MIT).

And who will get the money from that tax on blank disks? Everyone writing
software? No. Software developers who are big enough for the government
to consider them "software developers". People with the right credentials:
previous products, degrees in computer science.

Sounds like a great way to stifle software startups.

> The overnight reductions of SW prices by 50% or even 75%, a common

>
> - Moshe Braner

If someone is willing to pay exorbitant amounts of money for software, it's
not overpriced -- just expensive. There is nothing wrong with profit --
it provides incentive not only for a company like Lotus to build 1-2-3, but
for someone like Borland to build Quattro. If software development gave a
4% profit, who would write it? You'd put the money in the bank and get a
guaranteed 5.25% return.

> to own a computer. You should check out how the Polish resistance
> movement is making use of computers.

Come now, you are either short on imagination, or don't know much about police states. The Software Piracy Police go door to door, entering without warning, turning on your PC, and searching the disk for software. When they find copyrighted programs, they look for a manual with a valid license agreement for that software. If you don't have it, and the manufacturer can't find evidence of being a registered owner, they format your disk, and, depending how fiercely this police state chooses to enforce the law, executes you on the Chief Ed Davis portable gallows.

I think this would strongly discourage software piracy, don't you? I think it might well end it, even.

> <The enforceability of a law says nothing about the morality of the action

My argument is not with the morality of the law -- my argument is concerning the morality of software piracy.

> <Nothing is wrong with [copy protection] -- there's just too many people
> <out there who believe that stealing intellectual property is a right.

> when a law tries to change reality, it gets ignored. Expecting
> anything else is silly.

Aha! We finally get down to the crux of the difference of opinion. I view "intellectual property" as a valid position; you view it as an oxymoron. Here we must argue the nature of rights -- and doubtless

the divergence will become more extreme.

> BTW - I *don't* condone stealing software. While it's not immoral, it

>
> <mike

Does this mean if the law is changed, and we no longer recognize intellectual property (which would include copyrights of all sorts), that you will then feel it is OK?

[rest deleted]

I was debugging a fairly large BASIC program the other night, and ran
into a directory handling problem (I was using Carolyn Scheppner's code).
What I needed to do was to look at the file that was being produced,
but it is very difficult from BASIC. And when I got out of BASIC to
do a TYPE ram:temp, my list window size was lost.

Easy solution (on an Amiga 2000, with lots of memory), is to open a
CLI window and push it to the background before starting up BASIC.
When I want to look at the output file, I just shove the BASIC window
to the back and there is the CLI prompt, staring me in the face.

Simple, even for simpletons. And only on an Amiga.

Hi all,
I know you have all heard this question before, but I need someone to answere
this question, who knows for sure the correct answere.

What is the 40 folder limit?

Is it per partition?
Is it 40 folders in the root directory?
is it 40 folders for all partitions (intire hard disk)
What is it?
I have had people tell me it 40 folders for the entire hard disk.
Another person told me its 40 folders per partition.
Another told me it no more than 40 folders in the root directory.

Please Please Please someone give me the correct answere.
Thanks
Robert L. White

I bought a BMW K100RT two years ago to commute to work on. (Rain or
shine, I'd still recommend one.) I didn't pay extra for pistons,
brakes, or fairing...they weren't "gratis" either. But at least
they didn't cost extra.) They were part of the package.

Seeing this, I quickly valted to the phone and let my fingers do the walking. The courtious person who answered said the compiler isn't released yet. It's currently undergoing "final betatesting" and should be ready to be released in about two months.

I for one will be very interested in seeing how "Laser C" holds up to this new entry. I've used Aztec on several other machines and have found it to be a very professional, well written, -well-debugged-(!) product. If the ST version is anything like the other versions of Aztec, Laser C may find a very stiff competitor waiting in the wings...

I know what you are talking about as far as the Keyclick problem
goes. I used to have the problem, until I changed the Keyboard, which has
the newer version IKBD Controller. Havn't run into it since, but if it's
a TOS bug as I have read etc.. then your guess is as good as mine, as my
machine is on for about 8-10 hours/day, 7 days/week.

Typing speed? Depends.... Out of my head I can get to about 70 wpm
but if I have to copy from another hard copy, only around 40wpm. Though this
is by no means stupendious, I have over taken the wife this past year ;^}.

Allow me to correct two spelling errors. 1) My name is Meyer. I'm not
plural. 2) It's GNU, not GNE. And one misconception - most of it
wasn't from the Free Software Foundation.

<> Further, some of the best programmers I know (people who write working
<> device drivers without having hardware to test them on) don't write
<> software for a living. They maintain software for some group that
<> needs it to get their work done - and are allowed to give away their
<> changes and improvements to that software, and any tools they write to
<> make their job easier.
<
<How do they pay their rent? Buy groceries?

Please reread the above paragraph. The answer is there - "they
maintain software for some group that needs it to get their work
done." Neither they, nor the group paying them needs to sell the
software to make a living. So they give away much of it.

As a concrete example, I used to work for a petrochemicals consulting
firm. There attitude was that any software I wrote in order to do my
job could be given away, so long as it didn't contain company
proprietary information. That information was expertise in doing 2 and
3d gas flow simulations - which very few people aside from our
competition would be interested in. No problem. I gave away the
accounting package I did for them, as well as systems utilities and

other stuff. I even gave kernel bug patchs back to the vendor we bought the OS from. The company paid me for doing these things, and made a living that in part involved using these things as tools.

Other examples abound. Most work done for the federal government must be placed in the public domain. Most work done at state universities can be gotten for materials & labor. A fair selection of companies behave as the one I described above.

<It's very nice that there are some usable programming tools available that
<you can get for little or nothing. TANSTAAFL. (There Ain't No Such Thing
<As A Free Lunch...) Somebody had to pay for this, just not you. (If I
<remember correctly, that somebody is a University that supports this
<development. Farther down the line, particularly where state schools
<are engaged in supporting such work, the taxpayers pay for it.

True. And for the companies that give away software, the customer winds up paying for it. The point is that in many cases, it doesn't matter. You said it yourself:

<No...it gets written because there is a need (real or perceived) for
<the software, and because if someone is willing to pay for this soft-
<ware, someone else is willing to spend the time and energy to write
<and distribute it. With the expectation that their effort will be
<repayed in the future (along with their mortgage, rent, groceries,
<medical bills, schooling, ...)

In many cases, that repayment *does not* involve selling the software involved. It involves using it. I claim that that's the majority of the cases. You just have to know where to go to get the software (legally, of course).

<> No, copyright law - or lack thereof - isn't why software gets written.
<> It gets written because people need it, or because they want it. All
<> the copyright laws really do is restrict the distribution of the
<> software once it gets written.
<
<Copyright law exists (originally for printed material, later expanded
<to include software) *NOT* to restrict distribution, but to protect
<the producer's livelihood.

I didn't say why it exists - I said what it actually does. You're right as to why it came into existence, but that has nothing to do with what it actually does (intent vs. reality).

<In a scholastic setting, this sort of
<thing is called plagiarism and, so I recollect, is frowned on.

You've confused two issues. The copyright laws do more than prevent plagiarism. Plagiarism is the act of passing off something else as the product of your own work. That is frowned upon, and people doing that (even if they don't make an financial gain thereby) are <list all adjectives that have come up in this conversation so far>.

Copyright laws prevent you from giving something to someone else even
though you say who actually produced it. In a scholastic setting, this
is called "quoting", or a "reference," and is (to a limited extend)
encouraged.

1353. Ramdisk for Blitter TOS ? - (nf)

Newsgroup: comp.sys.atari.st
Date: 1988-01-26 08:43:00 UTC
From: sprache@ztivax
Message-ID: <40400004@ztivax.UUCP>
Source record: 254854

Hi netlanders!

Has anyone got a resetable autoboot ramdisk like that posted by Moshe Braner
a year ago ? I upgraded my TOS-ROMs to the new Blitter-TOS and now I
don't have a good working RAMDISK. Has anybody some experience with that
problem and can mail me changes for the old program or a new one?

Thank you in advance

Klaus Zuenkler
Siemens AG, Munich, W-Germany

1354. ICON language for the ST.

Newsgroup: comp.sys.atari.st
Date: 1988-01-26 12:52:23 UTC
From: NETWORK@FRSAC11.BITNET
Message-ID: <8801261322.AA01425@ucbvax.Berkeley.EDU>
Source record: 254855

I have a version of ICON 6.5 for Atari ST, with the following
change (from the previous version) :

.. Co-expression are OK.
.. Arithmetic overflow is handled.
.. system() work. (depends on your shell....)
(Most shell are not able to support system("ls")...try
command.tos, it may work...)
The shell is found by the SHELL environment variable.
.. Faster. (Should be better than any PC or AT at that...)
.. Usable from a shell or from the desktop.
(An environment (ICON or PATH) variable can locate the ITRAN, ILINK &
ICONX programs, or if not from a shell, a new switch in ICONT will
tell where they are.)
.. Handle environment variable for ICONX settings (Like the UNIX
(version) (getenv() works.)
.. Handle stderr redirection, just like the MSDOS version.

If you want to have it or test it, just drop me a mail.
(I will send it arc'ed and uue'coded, in several mail.)

regards,

Jean-Pierre H. Dumas

From: NETWORK at FRSAC11
To: INFO-ATARI16 at SCORE

Question #1 : How MWC's msh is discovering who called it ?
(desktop, or other...) it is in the local shell variable 'calledfrom'.
An other shell is able to tell the list of all parents programs...
The base page does not contain any backward pointer, so what is it ?

Question #2 : I read again the dev kit doc on shell_p, the posting
by A.Pratt about it, and I still wonder : what is it ?
I would infer it is a pointer to a string telling the file name of a shell...
I am right ?
What would be the use otherwise ?

1356. Trapping errors

Newsgroup: comp.sys.atari.st
Date: 1988-01-26 19:37:00 UTC
From: jrd@STONY-BROOK.SCRC.Symbolics.COM
Message-ID: <19880126193720.1.JRD@GRACKLE.SCRC.Symbolics.COM>
Source record: 254857

Can anyone tell me if there's a good way to trap the kinds of errors that usually result in bombs? I'm contemplating porting a debugger to the ST, but a fundamental piece of functionality is the ability to use my own trap vectors, or at least the get TOS to give control back to me with a pointer to the crash data. I would expect there to be some sort of OS call for this, but haven't seen it.

Related question: Does MUSHROOM.PRG work? Whenever I run it it appears to just dump a piece of the system stack, with no indication of the user PC or failing instruction etc. It then crashes itself with an alignment error. Is there a better substitute for MUSHROOM, or documentation on where to find the crash data and how to interpret it?

Thanks.

>Software is not an idea any more than a knife.

Really? Try making a backup copy of your knife, or sending it over a phone line. INFORMATION AND MATTER OBEY DIFFERENT PHYSICAL LAWS.

We are a long way from having legislation which deals realistically with the nature of information, and still allows its creators to earn a living. Pretending bits and atoms are the same is not going to help.

>The GNU people (particularly Mr. Stallman) might not continue with
>their idealistic ways if they had no other source of income beside
>the software that they're working on. (Who's paying their bills?)
>Is TANSTAAFL false? (Seems to work most everywhere else, except
>in politics.)

My understanding was that the FSF makes most of its money from SUPPORT for the otherwise free software. There are quite a few companies who think this a reasonable deal. Also, FSF sells EMACS manuals and such.

Obviuosly, companies which don't bother to support their products can't make any money this way - they would much rather stick the customers with the software and forget about them.

I actually made this remark in a PS at the end of my last posting,
but sonewhere between BITNET, ARPA and UUCP it got truncated:

I've got a feeling a lot of people havn't understood what Neil Harris
ment when he said Atari will be supplying the Blitter in the same
DIL housing as the 68'000: you'll have to piggyback (you know: solder etc.)
it on to the 68'000 in your machine (or get somebody to do it for you).
This is not just my interpretation, Mr. Stumpf of Atari Germany said
exactly that to a german magazine.

To: INFO-ATARI16 at SCORE.STANFORD

Hey, what this .inf file? I can assure everybody that UniTerm looks
for a number of things but not for a .inf file!

Files looked for in UniTerm 2.0a:

UNITERM.SET
UNITERM.TEL
Both files are searched for in the current working directory, this may
be in a slightly odd place with GEMSTART (I've never used it myself),
since for stuff started in the AUTO folder the cwd is possibly (I think
I tried this out once) the root directory of the boot disk.....

To: INFO-ATARI16 at SCORE.STANFORD

[How I love typing in subject lines from memory.......]

Just one remark: I've finished a much improved version of DLII, that
additionally to what the old version could do, it now:

- handles broken BPB's better
- can access the bootsector on any disk with 512B sectors
(0.25 could do that already)
- access raw floppies(with Track,Side & Sector)
- access raw harddisk (if the primary bootsector is ok,
but you can always edit that)
- editing of partition info (without destroying the rest
of the boot sector)
- is much more user friendly, you can short cut back to
the root if you are somewhere deep down in the directory
tree, all dialogs are scrolled and not redrawn where
possible, tries to handle odd RAM disks better (there
are some that are really crazy)
- will handle cluster sizes up to 4kB
- has a lot less bugs (hopefully)

As most people are aware (I hope) the version that is floating around
out there was never really released to the public and I still don't
really know what to do with the program, but there is a chance that
it will get the same status as UniTerm........

1362. Re: Software copy protection

Newsgroup: comp.sys.atari.st
Date: 1988-01-27 03:59:51 UTC
From: jhs@mitre-bedford.ARPA
Message-ID: <8801270359.AA00508@mitre-bedford.ARPA>
Source record: 254863

Several ideas (patents and actual products) have appeared in recent years that enforce copy protection not by appeal to honesty or the legal system but by providing a physical "doohickey" that has to be plugged in for the software to work. Such a device can be serial numbered and can use cryptographic techniques based on the serial number to enforce access to the software. It must perform a necessary function, so that the software actually *HAS* to access it, and get the right answer, which is a function of -- among other things -- the user's ID or serial number, in order for the program to function correctly. If "public key" cryptographic techniques are used, it should be feasible to make the contents of the "doohickey", including the cryptographic key, insensitive to discovery. I.e. the factory knows how to encrypt critical data and the doohickey knows how to decrypt it to get the necessary data values (branch addresses or whatever).

I suggest that what the industry needs is a standard for just such a doohickey that can then be routinely sold to computer buyers. Some enterprising company could sell the things and maintain the registry of users, charging a fee to the software vendors. Software dealers could be given the wherewithal to customize a program to run with a given individual's doohickey. I.e. a sealed-up PC type workstation with a magic ROM in it, or whatever. Some details would need to be worked out, but what I am proposing is that the necessary thinking and haggling be done to select a workable standard and get it accepted by the industry. Then everybody who wants their software protected against ripoff could subscribe to the standard and anybody who wanted to run their software would have to buy the doohickey and give the dealer their serial number in order to get a working program.

I think it would even be possible to sell programs that check the date and work only for, say, a month. Thus "evaluation" copies could be given away. This would probably require that the doohickey contain a realtime clock, but that should not add more than a couple of dollars to its cost.

In my opinion, adoption of such a standard would solve all of the problems being lamented here, at relatively small cost to the consumer. Does anybody know if one of the standards-loving bodies such as IEEE or ANSI is in fact working on a software protection standard?

-John Sangster / jhs@mitre-bedford.arpa

1363. Re: Shareware & Honesty (Was: Software (and other kinds of) copying)

Newsgroup: comp.sys.atari.st
Date: 1988-01-27 04:27:54 UTC
From: exodus@uop.edu
Message-ID: <971@uop.edu>
Source record: 254864
Cross-posted to: comp.sys.amiga,comp.sys.misc,comp.sys.ibm.pc,comp.sys.mac,comp.sys.atari.st

Instead of quoting the last three hundred people, I am going to give
my views...

How many people have paid more than US$100 for a software package to find
out that it does not do something that the 'other' package costing a little
more _did_ do? And how many stores have the broken shrink-wrap/no-return
policy (every single one in my area)? How many salesmen know what they
are talking about when they sell the afore-mentioned software packages?
(If they do know about the packages, they are creating them and not selling
them :-) An alternative? Yes, shareware.

Shareware is a great concept except for one small detail. It relies on
the honesty of the participants. In European countries, that wouldn't be
so bad (at least from my experiences...I have lived in Europe for 13 years).
In America, piracy has turned the software (and even the hardware industry
with IBM PC clones) industry inside out. No flames please, I am not
saying everyone is a thief, I am not saying Europeans are perfect,
no one take it personal. But if everyone who used Shareware and paid for
it, it might gain some respect. It is damned nice to be able to use a
piece of software for a day, month, couple of months before paying for it.
If only to find out what it can do, and also to figure out if it contains
any disasterous bugs that prevent it from being usable. How many people
would have bought the ST version of Wordperfect if they had know its flaws?
Not many.

Shareware as a concept has been introduced. Don't knock it.

1364. Re: OSS Pascal bugs

Newsgroup: comp.sys.atari.st
Date: 1988-01-27 05:47:00 UTC
From: REEVES@SLACSLD.BITNET
Message-ID: <8801270652.AA18933@ucbvax.Berkeley.EDU>
Source record: 254865

Recently, a few people have asked questions about OSS Personal Pascal. Here are a couple of files that I just downloaded from OSS's BBS. The number is (408)-446-3451. These should answer most questions that people may have. These are the most current that I found. Today's date is 26-JAN-1988.

```
*****************************************************************************
file BUGS1125

LAST UPDATED :: November 25, 1987

This is a continuing set of notes discussing bugs, etc., found in
Personal Pascal. As problems are solved, notes to that effect will
be placed here after the discussion of the original problem.

As new problems are encountered, these notes will be added to.

Thus it is probably worth reading these notes any time the "LAST UPDATED"
date (above) changes.

26 September 1987 PROBLEMS WITH AUXSUBS.PAS
-------------------------------------------

Even though we have been shipping Personal Pascal for only a week, we
already have had to make one update.

In order to determine which version you received, simply look at the info
box that appears when you boot into the Pascal manager. If you have
version 2.0, then you need this update. If you have version 2.01, then all
is okay.

Alternatively, if you are using a command line interpreter (e.g., Micro
C-Shell), look at the dates on the PASLIB and AUXSUBS.PAS files. If they
do not match the dates of most of the other files, then you have the newer
version and all is okay. If their dates are September 1st, they are the
old versions.

IF YOU HAVE VERSION 2.00
------------------------

You may download the two files PASLIB and AUXSUBS.PAS from here.

Fair warning, PASLIB is big. It will take perhaps 7 or 8 minutes to xfer
via XMODEM, even at 1200 baud. If you are running at 300 baud, you may
prefer returning your diskette to us for recopying (just disk A).

On the distribution disks, we placed PASLIB on both diskettes (to simplify
life for those using only one drive...we recommend erasing the copy on
drive A: if you have two drives...use your judgment on hard disks, Ram
```

disks, double sided drives, etc.).

Note: If you have version 2.02 or later, ignore this section.

==========

November 13, 1987 -- Known Bugs

BUG:

The editor does not work with MEGA ST machines or machines with the
new TOS ROMs installed.

FIX:

Fixed in versio 2.02. See PPQUESTS file (or first option in
the bulletins list) for how and when upgrade is available/coming.

TEMPORARY FIX:

In the meantime, use some other editor. (Sorry, no better fix.)

BUG:

The "create desk accessory" compiler switch does not work. Ditto for the
button in the compiler options dialog box.

FIX:

Same answer. Version 2.02.

TEMPORARY FIX:

See the "L"ibrary here for a description of how to make desk accessories
work under version 1.0x of the compiler. The same method works with
version 2.0x, possibly with a few restrictions may apply (see the library).

BUG:

Passing a function or procedure as a parameter to another subprogram does
not work. This is a code generation bug, since the compiler accepts the
source code just fine.

FIX:

Being worked on. Sigh. This one is the toughest so far.
NOT fixed in version 2.02, unfortunately.

BUG:

The editor colors (on a color monitor) are atrocious.

FIX:

No fix. This isn't a bug.

Oh, okay, it's a matter of taste. So we will soon supply a color changer.

Changed to black characters in version 2.02.
Marked blocks, only, become red.

BUG:

Using a call to MENU_TEXT crashes the system.

FIX:

An easy one! The declaration in the GEMSUBS.PAS file is incorrect. In that file, the last parameter to MENU_TEXT is given as a VAR string. This is wrong! Simply edit GEMSUBS.PAS to remove "VAR" from the declaration for this one routine. Ignore this if you have 2.02.

BUG:

Double clicking on a button in a dialog box causes a range check error or does strange things to my system.

FIX:

Atari didn't document this one very well, so we didn't catch it. If you double click on an exit button, then the DO_DIALOG call returns the index of that button WITH THE UPPER BIT SET!

In other words, if the user clicks on a button with a normal index value of 4, then $8004 is returned by the system. You may choose to take advantage of this (by using double clicked buttons for special purposes) or you may ignore this by simply coding something like this:
what_button := $7FFF & Do_Dialog(...)

BUG:

Where oh where is "OBJ_REDRAW"?? The manual lists it and I need it, but I can't find it.

FIX:

This was a case of the manual author and the software author not talking enough. You will note that the errors file on your master disk discusses the change in SHOW_DIALOG (it needs two parameters, not the single one shown in the book). Well, it turns out that SHOW_DIALOG is ACTUALLY identical with OBJ_REDRAW! So either change the name in your manual to reflect reality or add an OBJ_REDRAW routine to GEMSUBS.PAS that simply calls SHOW_DIALOG.

BUG:

The manual example for D_COLOR doesn't work.

FIX:

Just a documentation bug. Notice the formal description of D_COLOR's
parameters calls for a BOOLEAN value as the third parameter (text mode).
The example should thus have coded a TRUE for this value instead of "1".

BUG:

Dialog boxes created with version 2 have only a single line border instead
of the GEM standard double border.

FIX:

Dumb of us, but dumb of GEM, also. Do_Dialog is calling SETCLIP
just before executing the dialog. We are clipping to the size
of the "object" (the dialog box) as GEM tells us it is.
But GEM lies. But we believed GEM. So the clipping rectangle is too small.
Fixed in version 2.02.

In the meantime, the dialog boxes seem to work fine, even if they do look
a bit strange.

BUG:

The editor tosses its cookies when presented with some illegal files
(e.g., files transferred via XMODEM which still have pad characters on
the end).

FIX:

Version 2.02 should be safer on this, but...
We are still looking into this one, since even 2.00 should not
have had the problem. Sigh.

TEMPORARY FIX:

Load such files into our old (version 1) editor, go to the end of file and
chop of the garbage at the end, and then resave the files.

BUG:

GOTOXY in the "auxillary" routines does not work.

FIX:

Look for a source code patch called "GOTOXY" which should
appear here by December 1st. (That target keeps moving..sorry.)

TEMPORARY FIX:

GOTOXY is actually GOTOYX. Simply reverse your arguments and

it should work as you want it to.

BUG:

In the editor, pasting a block that has been deleted can cause strange
and wonderful things, such as system crashes.

FIX:

Version 2.02 improves situation, but may not be 100% fix.

Too complicated to do with other than major change. Look for
news of the upgrade in near future.

TEMPORARY FIX:

Avoid doing such things as marking a block in file 2, CLOSEing file 2, and
then pasting that block into file 1. Since file 2 is no longer
there, the marked block is no longer there either. Kablooey.

BUG:

PASAUX does not exist.

FIX:

That's right. It doesn't. Change your documentation, because it never
will exist. PASAUX is a part of PASLIB in delivered system.
(Early test versions had the two files separate, and the
documentation never got upgraded.)

BUG:

If you use the shifted function keys in the manager to access
the RENAME or ERASE capabilities, you get the wrong function.
The key functions are reversed.

FIX:

None yet. We even missed this one in 2.02.

TEMPORARY FIX:

Use the mouse. It works properly.
Or remember that the function keys are reversed.

==========

That's all for now. Let us know of things you find that are not on that
list. If you have submitted a report of an exotic bug, we may not be
listing it yet until we determine whether it is our problem or Atari's.

uuuuuuuuuuu
****

file PPQUESTS

PERSONAL PASCAL VERSION 2

As of NOVEMBER 25TH, 1987

ANSWERS TO COMMON QUESTIONS

QUESTION

How do I get an update to 2.02? (Latest version as of Nov. 25th is 2.02)

ANSWER

If you simply can NOT wait, we will update your disk (and this will NOT count as the free major update you are entitled to if you received and retained that little post card from us back in August). We ask that you return both disks and INCLUDE $3 FOR POSTAGE AND SHIPPING BOX! You may send cash (the amount is so small and we trust our people...and you) or stamps or check or... Just no charge cards, okay?

But if you can wait, see next answer.

QUESTION

When are the fixes for Mega ST's coming out?

ANSWER

They are done, part of version 2.02. We are now working on a patch program that will allow you to DL the fixes from here.

In the meantime, if you are desperate, see last question and answer.

QUESTION

Why does the file GEMSUBS.PAS have one size on diskette B and another size on diskette B?

ANSWER

The three files GEMCONST.PAS, GEMTYPES.PAS, GEMSUBS.PAS on diskette B are the "separated" versions of the single "GEMSUBS.PAS" file on diskette A, and they were put there to accomodate users who wish to compile version 1 programs without modification.

See the READ_ME folder on your master disk.

Note that in version 2.02 we decided to put ".OLD" name extensions on the three separate files (instead of ".PAS"). Less confusing.

QUESTION

Where is the disassembler on the Tackle Box disks?

ANSWER

SRM Enterprises says they will ship it (when it is done)
to all people who register their Tackle Box package...so send in your
registration card today!

QUESTION

Why did OSS say that Tackle Box would include 3 diskettes when there
are only 2?

ANSWER

Two reasons: We were told by SRM Enterprises there would be 3. Then they
got sneaky and archived files to shrink the diskettes down to 2. (And,
of course, there is the missing disassembler.)

We thought about doing the same thing with Version 2 Pascal, but decided
against it because we wanted Personal Pascal to be more accessible to
beginners. Hopefully, those of you with Tackle Box are more sophisticated.

QUESTION

How do I get the Personal Pascal manager to behave reasonably on a RAMDISK
or hard disk system? Mine seems to keep losing its place or is unable
to find the files it needs.

ANSWER

Well, the easiest way is probably to NOT copy the PASCAL.INF file to your
new default directory. Then, after bringing up PASCAL from that directory,
go through all the various options, etc., choosing the appropriate default
paths. Finally, save all these choices to a new PASCAL.INF file. In the
case of RamDisk users, you should then be sure that this particular
PASCAL.INF file is the one you copy to the RamDisk at startup time.

QUESTION

Where is this file called "PASAUX" that I have found a couple of
references to?

ANSWER

It doesn't exist. Change your documentation, because it never
will exist. PASAUX is a part of PASLIB in delivered system.
(Early test versions had the two files separate, and the
documentation never got upgraded.)

QUESTION

How do I make Line-A calls from Personal Pascal?

ANSWERS

SRM Enterprises is updating Tackle Box, again, to include a hefty section
on Line-A calls. Send in your registration cards to learn more about this!

But we also have a surprise: The version 2 compiler supports several
PRE-DEFINED Line-A calls! Why aren't they documented? Simply
because we didn't get around to translating all the German notes until
very recently. (Yes, the compiler itself comes from Germany. The GEM
libraries, manager, etc., are either completely OSS products or represent
major enhancements by OSS.) Once we have figured out how to use
all the subroutines, look for more info here.

****

If you have any more questions or other problems, I refer you to OSS. They,
after all, should be the final word.

Terry W. Reeves

'Compute!'s ST Applications Guide: Programming in C'
by Field, Mandis & Myers (ISBN 0-87455-078-5).

Cover price is $19.95 though it cost me 17.95 pounds here in the UK.
Worth it though. It has a lot of good code in it and several large
applications built from a toolkit of routines that should provide most
of the functions needed for ST GEM. Also useful is the fact that these
routines take account of the bugs in ST GEM where possible. Some good
ones for building resource trees within programs too.

1369. Print redirection routine

Subject: Print redirection routine

I am quite new, and still naive, to my Atari ST. I have programs that either only output to the screen or to the printer port! So as not to reinvent the wheel, what I'm looking for is an assembler or C program which would redirect the output of one of these programs to an ascii file rather than the printer. You see, I don't have a printer locally on my Atari. Thanks a million.

Merry Christmas,

Ralph P. Sobek

Source record: 254873

I also have VC.TTP version 2.1.a (85791 bytes long) and I have managed to use W correctly w/o extending the spread-sheet. At other times, it does cut off somewhere around columns G or H. What I haven't managed is to get wide output; VC seems to cut the printer output for a narrow printer into vertical blocks. Any solution to this?

In my version, the @avg command doesn't work properly: I can't save it (P) to a file since some parts of the program understand @avg and other @ave. If the source is available on the net I would sure appreciate someone mailing it to me. For what I want VC serves me well enough, but do better PD spreadsheet programs exist for the ST?

1375. GEMSTART = GFASTART?

Newsgroup: comp.sys.atari.st
Date: 1988-01-27 14:40:00 UTC
From: FRANK@FRILL51.BITNET
Message-ID: <8801281201.AA19131@ucbvax.Berkeley.EDU>
Source record: 254876

I've seen some messages asking how to start a GEM application from the auto folder. There is a program (not Public Domain unfortunately) from Gfa (the guys who put out Gfa-Basic) called Gfastart which has to be in the auto folder and reads in a text file which states the name of the program(s) to be started. You can also pass parameters or other filenames to the program to be started. I've been using it a while with Wordplus and it runs very well. It doesn't collide with other programs in the auto folder (like ramdisk or keyboard definitions) nor with accesories
If anybody wants to have the address of Gfa, please email me since I don't have it here at the moment.
Hope this helped a little.

1376. UNITERM ver. 2.0 DVI doc

1377. DVI format files

Newsgroup: comp.sys.atari.st
Date: 1988-01-27 16:41:42 UTC
From: edstrom@UNCAEDU.BITNET
Message-ID: <880127094142.25h@UcEdu.UNCA.AdhocNet.CA>
Source record: 254878

About the DVI format documents. There is a program on the Houston server called DVI.UUE which will allow you read DVI files on monochrome systems with 1 Meg minimum. So reading .dvi files isn't impossible.

What bugs me are the .tex files that are used to generate the DVI files and require access to TEX or LATEX or some such thing.

>If I copy a program which I would never pay for, the copyright holder
>loses nothing, since he wouldn't get any money from me anyway. In such
>a situation, the copying is illegal, but I would not consider it immoral.

This is exactly one of the cases in which "registering" with the
copyright office makes a difference. If you do NOT register your work
with the copyright office, you can only collect "actual" damages, which
in the above case is $0. If you register your work with the copyright
office WITHIN 3 MONTHS from publication you can ask for "statutory"
damages, which are decided in court and have NO set limit.

While I know of no case in which an individual has
been sued for illegaling copying software (but I might be wrong), several
authors/publishers have gotten large court awards for "company-sponsored
illegal copying". In all these cases the 3-month registration clause was
essential in getting the large awards.

>manage to get them changed.
>
I condone "stealing" any software that's copy-protected. Any software of mine will never be copy protected simply because it's fruitless to protect software- basically, if it is runnable, it's copyable. And if it's protected, it's an open invitation to try and break the protection. Maybe someday when I choose my life's career, my opinions on piracy will change. But my opinion of copy-protection never will. It's simply detrimental to the end user and merely a fun challenge to hackers.

But I must admit, I learned a hell of a lot about programming by learning to crack software. So maybe it's not such a bad thing after all. :)

1383. Re: Free Multitasking Kernel

Newsgroup: comp.sys.atari.st
Date: 1988-01-27 22:36:35 UTC
From: weaver@tut.cis.ohio-state.edu
Message-ID: <5425@tut.cis.ohio-state.edu>
Source record: 254884

[this is in response to David Beckmeyer's call for reasons for him]
[to release a 'free' multi-task replacement for TOS.]

David and net.folk:

Why should you release RTX into the 'free' domain (whether
you make it 'PD' or 'freeware', but that is another stupid debate
that should be moved to /dev/null)?

Why indeed. Because I want it! And other countless thousands
of ST users that want to use their machine for something other than a
graphics box that has no hope for a future. Multitasking is good,
humans multitask and computers should (and more often than not DO.)

Best of all, for Beckemeyer DevTools, it means money, Money
MONEY! Just think, real, honest-to-goodness manuals for all the neat
routines (and, uh, just maybe a real set of documentation unlike that
sold by a certain nameless company, with the initials a-t-a-r-i.

This would give BDT, at first anyhow, a small monopoly on new
multitask software until developers could begin. And, if Atari Corp-
oration finally sees something useful to be had, Mr. Tramiel could
open up his oh-so-tight pursestrings and go into an agreement whereby
RTX gets burned into new ROMs and BDT makes a tidy sum (and perhaps
becomes an "official" developer of RTX/TOS. Or, better yet, Atari
finally says, "gee, why don't we just get rid of the ROMs and make the
OS RAM resident" and not sell any machine with less than 1Mb. What a
great idea! Now we only have to make disks and we can release updates
every few months instead of every few decades.")

But those are my ideas. Send flames to the address below, or
if you feel exhibitionist send them to the net. I still like my ST,
but the next computer that I buy will be able to run Unix, and run
it well. The ST is nice, but it is unsupported by the company that
makes it, many crash frequently (including mine, but that's an
upcoming posting...) and are now overpriced.

I know, I know "bitch, bitch, bitch" but, as they say, you
know where the 'k' and 'n' keys are. Use them liberally, use them at
will.

Note above the original poster was quite specific when he mentioned
"those who keep and use..."
^^^
>As for fair, that means according to the rules. The rules (laws) in
>the US state that if you give somebody something, it's *theirs*. You
>can get neither payment nor the return of the thing, unless there's a
>prior agreement about such.

Most shareware comes with a usage agreement built in. I don't know
if the agreements, or if all of them, are exactly legal, but the concept
of honesty is distinct from the concept of legal. I can lie and be
dishonest without actually breaking any laws.

>Now, calling such people immoral and disgusting is fine. Those are
>value judgements, and I can't dispute them. Of course, I expect the
>same when I tell you that I find the very concept of shareware immoral
>and disgusting. I mean, you give somebody something, and then tell
>them they are immoral scumbags if they don't pay you for it?
>Especially when in many cases someone else is willing to give you the
>something very similar without calling you names if you don't pay for
>it.

This is not the intended agreement behind shareware at all. You are
expected to keep, and even distribute the thing with no strings attached.
If you use it beyond a trial period (I know, not specific), you are
"required" to pay for it or stop using it. That seems reasonable and fair.
If someone else gives you a preferred substitute for free, then use it,
and no one is asking you to pay for the original. Is this "concept" still

immoral to you?

The agreement is usually well specified within the software, and is probably covered under the rule of acceptance-implies-agreement laws. No one is forcing you to use the stuff, or pay for it.

>It gets written because people need it, or because they want it. All
>the copyright laws really do is restrict the distribution of the
>software once it gets written.
>

That's one way to look at it. While I agree that software would still get written even without such laws, I percieve the laws as giving those who create software a legal means to recover compensation when it is righfully due them.

All this, I guess is based on a fundamental premise... should someone who develops a software package (be it an individual or a company), have the right to charge others for the right to use the package? If the answer is yes, then the laws make sense in the context I mentioned above. If the answer is no, then I do believe there would be less software available, because many people could not afford to do this in their spare time, and many excellent minds are developed through the full-time process of software development. This is not the ONLY way we progress, and software would still exist, I just think it is a good thing that folks can make a living doing it too.

++using the mouse a lot) your machine will start clicking away as if you
++were holding down a key. (Assuming that you have the volume turned up, of
++course. Just how fast do you type, anyway, Rich? :-))
+
+ I know what you are talking about as far as the Keyclick problem
+goes. I used to have the problem, until I changed the Keyboard, which has
+the newer version IKBD Controller. Havn't run into it since, but if it's
+a TOS bug as I have read etc.. then your guess is as good as mine, as my
+machine is on for about 8-10 hours/day, 7 days/week.
+

The problem, as I understand it (and I do believe that I understand it)
is that the keyboard sends lots of bytes when mouse or joystick events
are being handled. If the routine that handles the packets takes a
little too long, the first few bytes of the packet are lost (since
the interrupt is inhibited) and the last byte(s) of the packet, which
are not lost, don't look like parts of a packet to the handler, they
look like key "make" codes. The auto-repeat is handled in software,
and since no break code has been received, the software decides that
it is time to repeat the "key", so a keyclick is generated, etc.
This is not really a TOS bug, just lack of flow control (and a poor
design decision in the software).

It could be that the new keyboard sends characters too quickly.

Any comments from Atari?

1389. article(s) from c't (the german computer magazine)

Newsgroup: comp.sys.atari.st
Date: 1988-01-28 02:52:00 UTC
From: COBB@BRANDEIS.BITNET
Message-ID: <8801281231.AA20114@ucbvax.Berkeley.EDU>
Source record: 254890

[this is forwarded from a friend]

Recently I received two issues of the German magazine c't. It has all kinds of interesting articles, so I'd like to share a short summary of them with you. I don't read German, so this is my approximation of the contents.

I would *love* it if someone who spoke German would post a summary each month...

Summary of c't articles concerning Atari ST; February 1988

p. 32 "Atari Laserdrucker SLM804" -- Review of Atari laser printer.

p. 40 "Echtzeitbetriebssystem PDOS fur Atari" -- Review of yet another multitasking-multiuser operating system for the ST: PDOS. Didn't really look at this much as I already have OS-9 ;-)

p. 48 "Btx-Manager Fur Atari ST" -- Review of a graphics program for mono STs under TOS.

p. 68 "Blitten mit und ohne Blitter" -- Demonstration program using the ST blitter.

p. 84 "Atari ST und Harddisk an einem Netzschalter" -- Seems to be a circuit that delays turning on your computer until after the harddisk has had time to spin up.

p. 106 "ST greift um sich" -- Programming article describing a driver program for a robot arm on an ST with a 68020 accelerator board running under RTOS-UH.

p. 126 "Billigloesung - Preisgunstige PC-Harddisk am Atari" -- complete plans for adding an IBM PC-compatible slot (they have a hard disk plugged into theirs) hanging off the DMA port. The slot interface is about 1.5" by 4" and consists of 3 connectors, 2 capacitors and resistors, and... 5 simple 74LSxxx chips. It looks like you could buy the parts for it at Radio Shack and put it together in an evening. Of course, it will take a while to type in the harddisk driver and formatting software, which is provided, written in assembler and Lattice C. The article is 10 pages long.

Page 14 talks about new products that Atari is releasing this year; the PC5 is an 80386 PC klone. Funny, haven't seen one of those on my local store shelves ;-)

In previous issues they have had articles about a 68020/881 board that piggybacks onto the ST motherboard and runs RTOS at 12.5 mhz. Next issue they plan an article on running TOS on the '020 board... they have patched the ROMS and could run 98% of the 300 programs that they tested with it.

I'm really excited about this stuff, and I would *love* to see someone making interface kits (hint hint). Also, a monthly column by someone talking about these articles would be welcomed.

I have no connection with c't (and I didn't even pay for this copy ;-)

I believe that you have this wrong.

David is talking about the underlying multi-tasking OS, not the C-Shell!

MicroRTX is _not_ the multitasking C shell, the mutitasking C shell
uses MicroRTX. I have the MicroRTX kit, and it works fine. I just
wish I had enough time to make all of the utilities that I work on
run under it properly, especially the Mark Williams symbolic debugger,
db, and the Mark Williams Micro Shell (msh). Unfortunatly, the PTB
(powers that be) don't want me spending time on it.

If MicroRTX becomes widespread, maybe I can get enough of an argument
together to get the PTB to let me do it.

1391. Setting seekrate for floppies

Newsgroup: comp.sys.atari.st
Date: 1988-01-28 05:16:54 UTC
From: med@druhi.ATT.COM
Message-ID: <2629@druhi.ATT.COM>
Source record: 254892

HELP!!!!

A few months ago, someone posted some info on how to set the seek rate for add-on floppy drives (e.g. I have a 5.25 360K Teac, which wants 6msec, not the default 3msec). I've tried setting the seekrate OS variable with no success (seems this is a Catch-22 variable - you have to set it before initializing the floppies via flopini, but you can't because flopini is called during boot - good design ;-(). Any info on the un-documented (but usable) locations to set for drive b: would be greatly appreciated.

I'll tell you why and how. First of all, yes we need this, and we need it for free or you can't convince people to use it. Or make it very cheap, like $15, put the manual on disk and that's that. *Very* cheap production for you. Alot of copies would sell since it is a nominal cost.

Then, how will you make money. The nominal fee is one. The Second way is to make a tool kit available for programmers and make this about $20-$30, include as many technical notes and helpful infom as possible.

I think that you would make as much or more money this way as any, and you would be doing the ST community a service. This is the way software is supposed to be distributed (I feel) and you would develop a good rep too.

1397. Laser Printers and the ST

Newsgroup: comp.sys.atari.st
Date: 1988-01-28 14:40:40 UTC
From: drs@bnl.ARPA
Message-ID: <320@bnl.ARPA>
Source record: 254898

I've seen the atari laser printer at the local stores and I have a few questions that the salespeople have not been able to handle.

First - does it make a great deal of sense to by the laser engine for $2K when right next to it is an HP going for $1.7K, which has .5 Meg of memory, and the ability to upgrade it to almost anything. (Postscript included). Is the quality of the Atari Laser so great as to outweigh all other factors?

Second - consider the following two scenarios. I buy a mono-mega4 and an atari laser printer for $4.5K, and lets say Word Perfect, a page publishing program.

-or-

I buy a mono-ST for .9K and a AST Turbo Laser for $3K -> for a total of $3.9K. I have the same software.

It seems to me that the second system is a BIG win. The laser has 3Meg of memory, 35 fonts, postscript, and a serial and parallel port so that it can be used with other computers. Most importantly, it seems to me that when one of the programs I use composes a page, I send it to the printer and let it worry about the printing - I get the ST back to do some useful work - essentially multitasking my home system (NO FLAMES!). I've seen more systems sitting at dealerships doing nothing but composing a page and otherwise being as useful as a doorstop. It also saves $600 - enough to buy a hardi disk.

Anyone care to point out the error in my thinking?

1398. C

Newsgroup: comp.sys.atari.st
Date: 1988-01-28 14:46:15 UTC
From: drs@bnl.ARPA
Message-ID: <321@bnl.ARPA>
Source record: 254899

In porting (or trying to port) software from the world to the ST I've run into three major roadblocks.

1) Operating system dependencies

2) Variable names lengths >> 8 characters

3) enum data type.

I have the original Megamax C and while I can deal with the first problem, the second and third are a pain for any real programs (postscript interpretors, smalltalk etc.) Has the new version of Megamax addressed these problems? Does any C compiler today offer the speed of Megamax with those problems solved?

Thanks

Andie,
Sorry I can't be of any help with BBS SW but I have used an Atari to receive satellite information. However, I'm not sure what kind of satellite or information you were particularly referring to.
I used an old 8 bit to extract telemetry data from the AO-10 amateur radio satellite, although most of the data stream conversion (Manchester code etc) was done in dedicated hardware.
There have been some articles (and maybe some net activity) about copying weather satellite and WEFAX on home computers with reasonable graphics.
To the best of my knowledge, most of the commercial C band satellites are heavily encrypted, DES, spread spectrum and so forth and I am pretty certain illegal (and probably fruitless) to try and decode.
There really is a lot of stuff radiating back towards earth! Hope this helps.

>Maybe in the near future (?!?) even WE will become worthy of the blitter
>chip. Let's all prey (in the general direction of Atari Headquarters) for such
>a miracle :-)

We pray.
Atari might prey (on us).
Not all of Europe has the blitter yet!

Since I have the floor, metaphorically speaking, I would say that a couple
of years ago Atari was well up front, and certainly ahead of Am*ga.
However, for the last year we have waited (in vain) for progress such
as the Blitter etc., and they have lost their edge.
Am*ga, meanwhile, has advanced a lot (even if they are affected by a virus).

I don't personally give a $*!t about 68020-based or transputer-based
future products: I do care about support and upgrade paths for products
that I buy. If I get the impression that a firm sells only different
products, each of which is then non-upgradeable to anything else then
I start thinking of going elsewhere.

Come on, Atari, get that bl**dy blitter out and available to ST users
EVERYWHERE.

1403. SH204 HARD DISK!

Newsgroup: comp.sys.atari.st

From: aegnor@bsu-cs.UUCP
Message-ID: <1972@bsu-cs.UUCP>
Source record: 254805

Well, this is my first posting to a newsgroup so be patient. I am a student at Ball State University in Muncie, Indiana. (Where?) and I have a dilemma on my hands.....

I was about to trade in my 800XL, and cassette drive (uck!) for a new 130XE and then the AD CAUGHT MY EYE, "NEW 520ST-FM Monochrome system, $299.00 with trade in of a 1050 disk drive, or $159.00 with the addidional trade in of a 800XL" My dilemma, I have a complete 800 system (modem printer the works) but now I see this ad, and am tempted to dump the whole kit and caboodle for a 520ST-FM system.

Recommendations? My friends and I think this is a very good deal, but I would appreciate the input of 'old AtariST' owners to let me know how they feel about this deal...by the by, the place is in Colorado, and I would have to ship them my stuff, (insured of course!) and they would charge for shipping me their stuff, (by weight) so lemme know what you guys think, and it will (maybe) salve my consience, and convince me to buy the 520ST-FM (with built in drive, I like this feature!) and dump my old workhorse... though, I have only had my 800XL for 2 years.

Well, thanks for listening!

>a situation, the copying is illegal, but I would not consider it immoral.

I rather strongly disagree with your point of view. You are assuming that
the only 'value' involved here is the cost of physical items. If I extend your
reason to the general case, you are saying:

If I obtain a copy of something that is owned by somebody else, I
have done nothing wrong. It may be illegal, but it is not wrong, since
what I have done has no affect on the owner of the thing. I have not
stolen any*thing*.

This assertion is false. Making a copy of something *can* affect the owner! And
you are stealing some*thing*, even though the thing being stolen is not
physical. To make it obvious, consider the case where there is a small class
of people that can and will pay for X, and a much larger class of people who
cannot affort to pay for X or are unwilling to pay for it. If everyone in the
larger class of people makes a copy of X (where X is 'intangible property'),
what might the results be?

- The value of a copy of X may decrease as far as willing purchasers
is concerned. Copies of X are rarely of identical quality to
the original. (Examples: For software, the documentation is
rarely copied at the same quality. Art: a photograph of a
painting just isn't the same!)

- The more copies of X that exist, the less a single copy of X is
valued. Simple supply and demand economics, if nothing else.

- The rightful owner of X may have to deal with endless inquiries about
X from people who have never paid for it. Even simply saying
"no, I won't explain" costs something, especially if it must
be said a million times!

- The owner of X has the moral right to say 'you may not have X if you
will not pay for it, because sales of X are my livelihood'.
If you are unwilling to pay for X, you should be able to live
without it. If you can't live without X, it is worth more than
$0.00 to you, and you should be willing to pay for it! Just
because you would like X's owner to be altruistic and give you
a copy does not place any moral compunction (sp?) on X's owner
to do so, nor does it give you the right to *take* a copy.

When you make a copy of something that the owner does not want copied, you
are stealing:

- The owner's right to control the distribution and use of X
- The owner's right to make a living from the distribution and use of X

There are many positions that can be held wherein such property rights are
given over to some other party (the State, the People). But in all cases, the
original creator must be *paid* in some way for the transfer of these rights.
If this is not done, society is left without all forms of professional
intellectual creation vocation. This would be rather serious!

Here's a short list of people who earn their keep by investing time and/or
$$$ in the creation of intellectual property. To the extent they lose control
over that property, they will find it hard to make enough profit to stay in
business. *MORALLY*, they have the right to their wages, just like you do for
the time *you* put in at work!

- The obvious: songwriters, authors, artists, programmers, etc.
- Money market-watchers (contents of newsletters)
- Market research firms (contents of research reports)
- Product testing companies (test reports)
- Architects (blueprints, building designs, etc)
- Professional cooks (recipes in cookbooks, etc)
- etc.

That's enough from this guy's keyboard for now.

Pete

You're forgetting "through USENET". This is the way I get most of my
shareware, and it is most definitely unsolicited, though not unappreciated.

1408. HELP!

Newsgroup: comp.sys.atari.st
Date: 1988-01-28 18:55:41 UTC
From: keithr@vice.TEK.COM
Message-ID: <2234@vice.TEK.COM>
Source record: 254809

I was wondering if anyone out there has had any
experience using Timeworks Data Manager. I am
using it to do my church's membership list.
There are about 350 records in my database with
9 columns. When I try to add a new column it
replaces the titles of existing columns with
non-ascii characters. I am running the lastest
version which I believe is 1.1, I not sure though.
The first version of Data Manager was full of bugs
and I was wondering if this might be one. The only
thing is that I am running it on my 520, but I tried
it on a friend's 1040 and it worked fine. Could it be that
I don't have enough free memory? I checked the status
and it says that I have 198k of memory left. Can
anyone help me? If Data Manager is "flakey" could
someone recommend a good gem-based database. I've
tried db master and base two, but aren't as flexable
as Data Manager.

Thanks in advance,

Keith

Guys,
It is not a law that varies from State to State, it is a Federal law,
handed down by the Federal Government, not local or state government.
If someone sends you unsolicited material in the mail, it is simpily yours
to keep, You are under no obligation to return it what-so-ever.
Call your local postmater and ask!
But, what if someone else sends for something and fraudently puts your
name and address dowm. For example, what if someone fills out one of those
magazine subscription cards and places someone elses name and address on it
without that persons knowledge? (This is of course a "bill me" order, not
a pre-pay) They usually send you 2 or 3 issues before that stop sending due to
failure to pay. ??????????

I called Megamax today - and spoke with a most gracious receptionist.

Unfortunately, she had bad news - Laser C wouldn't be shipping until mid February or early March. (In December, they were to ship in January). Seems that the printer is taking longer than estimated.

I guess they use the same printer as OSS and Atari. - Probably Gutenberg.

sigh

What about minix???? Granted it isn't exactly free, but at US$80, its pretty close. I saw an article which said shipping in June.

Minix will probably fix the 40 folder bug too :-).

It will probably port to the amiga quite easily too. There, no more my amari is better than your your atiga wars.

Time to buy a hard disk!

Late in 1986 I had received a copy of a nice little fractal drawing program written (or at least distributed by) the people at CAST, the "Calgary Area ST user's group" if I'm not mistaken. It was fairly simple and just did plots and zooms of the various dragon curves in "full" colour and was supplied in the public domain. Of course, for a FULL, WORKING version with the source, you had to send $25 to the group etc., etc...
Recently, it became usefull for me to have such a program's source code, but needless to say, someone had run a MARKBAD on the hard drive I had it on (a testimonial to the use of TURTLE I suppose...). I've gone looking over the last few days for a copy on the local BBS's, to no avail, and the only thing on CANADA01 is MANDALZOOM which would require MUCH modification to be usefull to me. Since the only address I've seen for the group was posted in the program, I'm out of luck trying to contact them.
So, does anyone out there have the program I'm refering to? I would be greatly in debt to anyone who could help me find it :-).

DCFormat has an option to write a "hard disk override" boot sector to a
floppy. Usually the floppy boot code essentially passes control over to
the DMA booter.

>
>It's a hoax.

Well, when I started this thread (amazing how conversations grow
sometimes) I ended with a comment about shareware being a good idea
in some ways -- Mainly because it took advantage of the fact that
software is so easily copyable.

But as with any product. In order to get money out of the public you
have to provide some good product. Either (as in the case of disposable
razors) the cheapest form of the product, or a good quality product.
Bad shareware doesn't get money. Good shareware will get money. Mediocre
shareware will get some money.

It's not exactly a hoax and neither is it moot. A different system
of distributing software needs to be developed ... one that will allow
authors reasonable returns ... one that will allow people to make backup
copies of software, give copies to friends, whatever ... maybe it's
the holy grail.

BUT IT REALLY GRIPES ME THAT I'VE GOT THIS MULTI-TASKING MACHINE (Amiga),
AND A LOT OF THE SOFTWARE WON'T MULTI-TASK BECAUSE OF SOME SORT OF
COPY PROTECTION SCHEME THAT!

ahem

seriously ... I'd like to bring up Little Computer People ... play with
it awhile ... put it in the background ... come back to it later ... etc.

that's an example of the stupid things that happen because companies
have to copy-protect their software ... there are many other stories

1416. OMNI-RES monitor emulator "review"

Newsgroup: comp.sys.atari.st
Date: 1988-01-29 03:56:16 UTC
From: SOFPJF@UOGUELPH.BITNET
Message-ID: <8801290427.AA04520@ucbvax.Berkeley.EDU>
Source record: 254816

I bought this thing called OMNI-RES. It allows you to use
LOW and MEDIUM -res programs on a monochrome monitor, and HIGH-res
programs on a colour monitor.

The good new is: It works on anything that doesn't boot cold off
the disk without peeking in the AUTO folder. It really does! (I can
attest to the fake-colour-on-mono mode anyway).

The bad news is: 1) It is kinda slow in some modes, and VERY slow
in others. Definitely not for your fast-action arcade games. The
mouse does NOT move around as smoothly as it should.

2) No matter how many gray scales you use (16 on the largest and slowest
emulation), some colours are going to be very close to others in
intensity, so it takes a bit of fiddling with bit plane selection and
CONTROL.ACC palette twiddling to make some programs usable.
(By the way, I have no real conception what BIT PLANES are and would
love a layman's description - please post to the net, as I'm sure I'm not
the only one).

- (As an aside...)
So now I found out something that I guess I kinda already knew, and
you colour monitor folks do without even thinking about it:

** ON a MONO system, you have to RESET to install a new set of desk
accessories. This means going through all your AUTO stuff (Ramdisk,
clock-set, you-name-its), BUT On a colour screen you use "SET PREFERENCES"
and change the res, and HEY PRESTO - New ACCs.

Q: Can any of you wonderful and thoughtful hackers out there with full
documentation think of a nice way to FAKE A RESOLUTION CHANGE, so that
GEM/TOS loads in another set of ACCs? Maybe even something that stays
resident (if it's only a couple of bytes long) and does it's thing
upon some unlikely keystrokes (alt-ESC or some such), or click on the
Atari symbol in the DESK menu...

Gee that would make desk accessories almost USEFUL!
- (... as I was saying:)

The program comes with 8 flavours, patches for the Mega (and other ROMs
on demand), and a not-too useful "switcher" that selects the type of
emulation to boot with this time. (I would have preferred a CONFIG file,
and just re-name the files (.PR <=> .PRG) 'by hand').

The small print says that the programs HAVE to run from the AUTO folder
(yep, I found out the hard way), or strange effects (and bombs) occur.
This is because it has to get it's paws on things before GEM does.

Copy protection is unique: It allows you to make copies, then you can "Key" the disk using a program they supply and the original (or other "Keyed" disk?). One of the key disks must be in drive A at BOOT time, even if it contains no visible programs. This may make it un-popular with hard-disk users.

Although this won't stop a dedicated hacker, this "reproducible key" method does do what they want, which is to allow backup, but slow down illegal distribution (at least until some SOB 'cracks' it - which I hope never happens - The authors have put a fair amount of work into this thing).

Anyway, as for the program, I DO like the idea (but wish it was faster), and it's a nice $50 (Cdn) addition to my set of tools.

Omni-RES is made by "Hypertek/Silicon Springs Dev. Corp."
#120-1140 Austin Ave; Coquitlam B.C. Canada; V3K 3P5
(604) 939-8235

As always, the standard disclaimer is that I don't have any interest in the company above, and my opinions (such are they are) are my own.
/PJ

1417. Re: Uniterm version numbers - What's the latest?

Newsgroup: comp.sys.atari.st
Date: 1988-01-29 04:04:58 UTC
From: hakanson@mist.cs.orst.edu
Message-ID: <2202@orstcs.CS.ORST.EDU>
Source record: 254817

The latest that Simon Poole has distributed is 2.0a 006. Since he emails them directly to me, I generally have the latest (and make them available for FTP here when they unpack and run ok). Simon has repeatedly asked people to NOT post UniTerm to the net, and to leave it to him to do that, since only he knows when he will come out with a newer version.

As an example, I just got a note saying 2.0a 017 is on its way here. If I had posted 006 (even a couple weeks ago), the effort and Usenet resources (UniTerm has grown to be quite large, especially if you include the whole manual) would have been wasted. This is the kind of situation we try to avoid. When Simon thinks v2.0a is stable enough, I'm sure he will post it to the net. And you can be sure that I will not post UniTerm unless Simon asks me to do so.

Meanwhile, if you can send email to a BITNET site, you can retrieve UniTerm from LISTSERV@CANADA01.BITNET. Sorry I couldn't help more.

Oh, and just to whet people's appetites (I'll put this up for FTP as soon as I get the whole thing here):

Date: Thu, 28 Jan 88 16:23:32 GMT
From: K538915%CZHRZU1A.BITNET@cunyvm.cuny.edu

ReadMe for UniTerm V2.0a 017 <-|
---------------------------- |
|This number is displayed on the
'About UniTerm...' dialog box and
indicates the "Edit Number"

Changes 2.0 to 2.0a

General:

At last colour works again. The colour registers are saved and restored, so there shouldn't be any mixing up of your normal color settings anymore (this is important, since in some future version of UniTerm more fancy things may be done :-)).

V2.0a 003

Fixed an error in loading the setup file (the tabs didn't get set).

V2.0a 004

The tab dialog trashes (for some deep unknown reason in GEM) the line-a
variable source_y, fix: set it before every invocation of txtblt.
Expanding and shrinking box added before and after each (nearly) dialog
(this is really stupid, since it just slows things down).

V2.0a 005

<Alternate> works slightly different again (Meta mode stays the same):
If no command value is defined (command = 0) for the key, the character
provided by the BIOS is used for output, hopefully this will set an
end to all the various complaints about the way it worked previously.

V2.0a 006

One file didn't get recompiled after I sorted one of the dialogs in
UNITERM.RSC, lead to a major distortion of the popup :-). Fixed for
most people with a patch and for myself with recompiling.

V2.0a 007

Changed a few internal things in Kermit, which may lead to some
user-visible changes one day........

V2.0a 008

The problem with the cursor disapearing now and then
(happend sometimes after a change in the LED's), has hopefully
been fixed.

V2.0a 009

<Shift><F5> couldn't be used as a downloadable key, due to a typo
in the code.

V2.0a 010

Changed the 'Show Space' code so that it uses the same critical
error handler as the fileselectors, one less place where you can
bomb UniTerm (just to show off, find any other program that you can't
bomb by using a fileselector on an empty floppy drive!).

The Light<->Dark buttons in the Terminal Setup 1 dialog have changed
from totally useless, to semi-useless. This switch is really redundant
since from V2.0a on UniTerm actually keeps it's own complete copy
of the color pallette, so it's much more resonable to change
fore- and background color with the control panel, none the less
V2.0a 010 has been fixed so that changing the state of the
buttons inverts the screen (but there is no fixed relationship to
what is dark and light).

V2.0a 011

Changed a few things in the organisation of the internal screen buffer,
double height/width characters should work more consistent with the
different character sets available, in particular implementing NRC sets
should be a lot easier now. Some useless tech info:

Information stored per character (50 Rows * 132 Columns):

1 byte : character
1 word : character set and attribute info:

```
-------------------------------------
| Bit | Function |
-------------------------------------
| 15 | 1 = Protected |
-------------------------------------
| 14 | |
| 13 | Unused |
| 12 | |
-------------------------------------
| 11 | Character Set (nibble value)|
| 10 | currently values from 0 to 8|
| 9 | are legal (but not all are |
| 8 | used) (this is what changed)|
-------------------------------------
| 7 | Attribute |
| 6 | 0 : no attributes |
| 5 | 1 : bold |
| 4 | 2 : blink |
| 3 | 8 : underscore |
| 2 | 32 : inverse |
| 1 | |
| 0 | |
-------------------------------------
```

The first VT300 escape sequences have been implemented:

ESC?67h Backspace sends ASCII BS and Delete sends DEL
ESC?67l Backspace sends DEL and Delete sends BS

this is not quite how it's implemented on a VT3XX, since
there it only effects the Backspace key.

V2.0a 012

New macro commands:

%MESSAGE(string)

Displays 'string' on the statusline. If 'string' is empty the
normal statusline is restored.

%SUSPEND()

Displays 'Press any key...' on the statusline and waits for
a keypress (particulary useful for people that want to have
a single key noscroll button).

%INLINE(mode)

Reads a line from the keyboard (until <Return> is pressed or a
maximum of 80 characters are read), if 'mode' is TRUE the characters
are echoed. The line read is copied into $TEMP.

V2.0a 014

Small changes to the dialer:

- if the number and macro field is emtpy, the dialer returns straight
away
- if the number field is empty, but the macro field has an entry
the macro file is executed

A tip for people that want the macro to handle the waiting for the CONNECT
or whatever it may be message, just leave out the 'Connect msg' entry. The
dialer will then immediatley start the macro file after sending the number
string (this is not 014 specific!).

V2.0a 015

At last I've produced a documented interface to the internal buffers etc.
of UniTerm. Access is through the macro variable $VARBLOCK (short $V), to
see how it works have a look at the stupid sample program, to start
the program reserve something like 20kB of system memory and put the
following string on one of the function keys:

%RUN('UNITEST.TOS',$V)

Don't try this if you have started UniTerm from the CCD/OSS Pascal manager,
it's sure to go wrong (this is not a bug in UniTerm!).

$VARBLOCK is a string containing the decimal address of following Pascal
record (should be no problem using a C struct instead):

```
{ParmBlock contains buffer addresses etc. to be passed on to other
processes}
ParmBlock = Record
PBLength : Integer;
{Length of ParmBlock in bytes, handy as a version
check}
PBFlags : Long_Integer;
{Not used yet}
PBTextScreen : Long_Integer;
{Address of text screen}
PBGraphScreen : Long_Integer;
```

```
{Address of graph screen, same as PBTextScreen
if not available}
PBScreenBuffer : Long_Integer;
{Address of buffer for screen ops etc.}
PBTransBuffer : Long_Integer;
{Address of buffer used for the various file transfer
protocols}
PBTransSize : Long_Integer;
{Size of the transfer buffer (in bytes)}
PBTransPtrAdr : Long_Integer;
{Address of the pointer to the current
position in the buffer}
PBHistBuffer : Long_Integer;
{Address of the history buffer}
PBHistSize : Long_Integer;
{Size of the history buffer}
PBHistBotAdr : Long_Integer;
{Address of the pointer to the current bottom
of the history buffer}
PBHistPtrAdr : Long_Integer;
{Address of the pointer to the current position
in the history buffer}
End;
```

New fields will be added at the end of the record, so applications just have to check the length field to know what facilities are available. More information will follow under seperate cover......

V2.0a 016

Initialized cursor properly after ESC Pu.....ESC\ command (host command to have a line executed by UniTerm's macro processor). One remark to this escape sequence: it is a bit of a security hole: a nasty person could get UniTerm to delete you entire disk this way.....
Added a call to form_error after a PExec that goes wrong, is not very helpful (TOS Error #39 is not enough memory).

V2.0a 017

Checked that every 'Case' statement has an 'Else' label if the range of the selector variable is larger than the range of case labels. This started causing trouble with release 2.0 of OSS/CCD Pascal, prior to 2.0 non-matched values just caused a fall-through, in 2.0 depending on how the the compiler is feeling this causes a lot of bombs (possibly random code being executed). One place where the problem turned up was in the escape sequence ESC[2m , 2 is actually an illegal value which didn't have a corresponding case label (BTW there were only 5 'Else's missing in 500kB of Pascal source).

Gee I guess my last message didnt get here.
I will try it again.

I know This has been answered here before, but I didnt have a hard disk then
So I didnt pay alot of attention.
What exactly is the 40 folder limit?
Is it per partition?
Is it 40 folders max in the root directory?

Thanks in advance
Robert L. White

1421. Re: Software (and other kinds of) copying

Newsgroup: comp.sys.atari.st

Consider the following analogies:

I own a rare postage stamp. It is the only stamp of its kind known to exist, and its value is a strong function of its rarity. If you now discover another instance of my stamp, the value of my copy goes down.

I own another rare postage stamp, but not as rare as the first one; there is another known instance of that stamp, which you own. There is a fire in your home and your copy of the stamp is destroyed. The value of my copy goes up because its rarity has just increased.

Perhaps the analogy between the stamps and making copies of software is a bit strained, but the point is clear; the value of something I own can decrease simply because it becomes more common and easy to get, without anything actually happening to my copy or copies.

It was my understanding that the same things applied to software as
any copyrighted matter in that it is legal to copy something for home study.
This is what allows you to copy some pages from an encyclopedia in a library.
You should, therefore, be allowed to evaluate software legally.

Federico (sic) and others you may need to know:

If you boot your machine with the HDisk off and then manually run the AHDI
driver you get booted up from an alternative device and still have access to
the harddisk. This is how you deal with the above problem.

Also, DESKTOP.INFO is written to the boot device.

>1977 trs-80!

A long, long time ago, a company named Atari wanted a windowing system for its hot new computer. They came to Digital Research, since unlike some other companies, we had experience designing operating systems for 680x0 based computers. And we had Crystal (which became GEM).

And we already had an 'okay' 68000 operating system, CP/M-68K, and we were (then) working on a multitasking, multiuser version of the same called "CDOS/68K". But GEM ran only on MS-DOS machines, and sorta depended on that file structure. Hmmm. So we considered changing GEM...

But then a systems programmer said that _he_ could write a new operating system in a month that would look just like MS-DOS from a functional standpoint, and would be great and perfect and peachy-keen. And he did - pretty much alone. And since Atari was in such a hurry, they took what we had before all the horrid problems in it cropped up.

And later we fixed all those problems and then forgot about it. I don't think there's anyone here still working on GEMDOS.

*** NOTE: THESE COMMENTS, ET.AL., ARE IN NO WAY SANCTIONED, CONDONED, OR REPRESENTATIVE OF DIGITAL RESEARCH, INC. THEY MAY EVEN BE WRONG. I JUST WANTED TO EXPLAIN WHY AND HOW DRI COULD RELEASE SUCH A SUBSTANDARD O/S.

In MS-DOS there is a location which contains the \ character
so that if you change the contents to / then you have a decent directory
delimeter. I would like to do this on My 1040. Is this possible?

****Get out your fire extingushers.******

My guess is that while they were introducing hard coded limits
into the OS they managed to see that the user had some alternatives in
MS-DOS and then they eliminated them.

My-My It is funny to see a terminal melt while I flame overworked
software engineers.

1427. On the Road

Newsgroup: comp.sys.atari.st
Date: 1988-01-29 18:23:31 UTC
From: neil@atari.UUCP
Message-ID: <959@atari.UUCP>
Source record: 254827

My position in Atari is in the process of changing. I've been appointed as Director of Sales & Marketing for the East and Midwest Regions. This covers all the territory from Maine to Virginia and west through the Dakotas.

As you might imagine, this is a lot of ground to cover. At the moment we have 3 district sales managers, 4 distributors, and 2 rep firms in the territory. My job is to get all of them working as hard as possible to strengthen existing dealers and to open good new dealers for Atari computers.

What this means to you is that I won't be quite as active here as I've been for the past few years -- for one thing, I'll be on the road quite a bit. And at the moment there's a mountain of paperwork accumulating from all over the company as I try to get a handle on my territory.

People here are both congratulating me and offering their condolences. Guess I have mixed feelings also. It's a great opportunity for my career, and also a major challenge considering the events of 1987. Let's see how it goes.

Regarding my prior responsibilities, the outcome remains to be seen. I'm giving up national advertising, which is being handled by Mel Stevens (not that there was anything happening at the moment, but we were generating plans quite a bit and talking to all kinds of salespeople). I'll still be doing some PR, since there's no good fallback person here for that, although I'm delegating as much of that to the PR agency (Neal Amidei and Co., 415-788-1333) as possible. Back to PR -- I urge all software developers to stay in close contact with our agency. It's their job to serve almost as much as your agency as ours. They're instructed to help you in any way they can. They are fully equipped to give demos in their office, too.

One last thing -- I'm making a trip to New York City in a couple of weeks. People in that area may want to listen to radio station WBAI (FM 98.5) from 7:30 to 8:30 PM on Sunday the 7th. I'll be the guest on the Personal Computer Show, a talk show, discussing the ST, Mega, and Abaq.

If you are in my territory and have something to bring to my attention, please use email on GEnie, BIX, or CompuServe to contact me. I'd be glad to help in any way I can, but it will be hard for me to access Usenet from the road.

Thanks to all of you for your help and support in the past few years. I'm hoping to continue to receive it in the future.

1428. GENST (Assembler) -- Help Needed! (please?)

Newsgroup: comp.sys.atari.st
Date: 1988-01-29 18:28:23 UTC
From: tim@brspyr1.BRS.Com
Message-ID: <2502@brspyr1.BRS.Com>
Source record: 254828

Could someone out there please lend some assistence with the use of the GENST.PRG program? I picked it up the other day from the Atari BBS, and I can manage some of it, but have some questions.

* The version I got was 0.90 dated 1985. Is this the latest version? If not, what is and where can I get it?

* There was NO documentation that I could find on the Atari BBS for this program. Does any exist? How would I get that?

* I was able to figure out that you use "DS" in the opcode space to define a space of n words, and "DC" to define a word constant. How do I define a string constant? I tried a bunch of things, but all I could get to work is something like:

DC "Th","is"," i","s ","a ","co","ns","ta","nt"

I would rather do something like:

DCC "This is a constant"

* When doing an ASSEMBLE with listing going to the screen, there seems to be no way to stop the scrolling of the output, and once it is done the mouse pointer goes away, so I can't use the slider bars on the window to scroll the listing back. Is there any way to either pause the listing while it is going on, or scroll back and forth within the listing once the assembly is finished?

Thanks for any help anyone can provide.

The $100 plus price tag for a RGB to composite cable seems a little steep. Elektor magazine (it from the UK) published a circuit to do this called Atari ST to SCART adaptor in early 87 (march I think). SCART is an analog RGB interface with composite sync - I think this should do what you need. Parts cost is under $20.00

An article by olsen@ll-xn.UUCP (Jim Olsen) says:
<In article <229@wright.EDU< jholbach@wright.EDU (Jim Holbach) writes:
<< I am amazed at how much discussion the topic of copying
<<still generates though... It still comes down to theft...
<
<Unauthorized copying is not theft: it is infringement of a statutory
<monopoly. You may think that unauthorized copying is a bad as theft,
<but you confuse yourself when you say it _is_ theft. The two crimes
<are quite distinct; this is why people treat them differently.

Sorry, it is a form of theft. As shall be demonstrated.

<If I copy a program which I would never pay for, the copyright holder
<loses nothing, since he wouldn't get any money from me anyway.

"If I illegally tap into the cable TV lines but would never subscribe
to cable TV, the cable company loses nothing, since they wouldn't
get any mony from me anyway." Let's say you use this logic.

What you have committed is called "theft of services". You will
be fined and/or jailed when you are caught. Software provides
its user with a service, just like cable TV or a time-share
system. The fact that you only pay once for the service (as
opposed to monthly as with Cable, or as-used with time-share)
does not change that basic fact.

> In such a situation, the copying is illegal, but I would not
> consider it immoral.

"Immoral" is a value judgement. It is certainly unethical.
And it SHOULD (and is) illegal for very good reasons.

Although their is dissent about whether some things should
be written into law or not, there are other things about
which their is no doubt about whether they should be illegal.
The criteria by which these must-be-illegal things may be
recognized is simple : Would the society (as the members of
the society perceive it) become untenable if they were not ?

By this reasoning murder must certainly be illegal : few
of us would be willing or able to live in a society where
indiscriminate manslaughter was legal. Theft, extortion,
kidnapping, enslavement, torture, rape, assault : try
to imagine a society where any of these is legal. Would
you try to raise a family in such a society ? Or even live ?

To modern Americans, theft-of-services meets this fundamental
criteria. Without theft-of-services being illegal, there
would be no cable or network TV, no time-share systems,
no telephone network, no Consumer Reports, no garbage collection,
no mail office, no public transportation.

In a purely socialist society, perhaps theft-of-services
need not be a crime. But in a capatilist one, it has to be.
Even the process of invention is only a service : infringing
on a patent is really the theft of the inventor's services.
Read some of Ben Franklin's writings on the need for a
Patent Office if you need further enlightening.

Aha! But suppose there were only 3 or four copies of X C-compiler out.
It would have very little value. This is because software is not archival.
With any luck, it gets better and better, and eventually, old packages
will become obsolete, replaced by better programs. If a game is pirated,
it's intrinsic value does not go down. BUT its market value plummets,
endagering the well being of the publisher/writers.
Nuff said...

Source record: 254837
Cross-posted to: comp.sys.amiga,comp.sys.misc,comp.sys.ibm.pc,comp.sys.mac,comp.sys.atari.st

[Followups have been pointed to comp.sys.misc.]

In article <160@octopus.UUCP> pete@octopus.UUCP (Pete Holzmann)
demonstrates the common fallacy of thinking that anything you can do
can be turned into a right:

< - The owner's right to control the distribution and use of X
< - The owner's right to make a living from the distribution and use of X

The first of these isn't a right, but it is legally granted privilege.
I happen to think the laws in this case are wrong.

The second isn't a right, or anything else. The law grants you the
right to _try_ to make a living distributing X. It doesn't say whether
you'll succeed.

< - The owner of X has the moral right to say 'you may not have X if you
< will not pay for it, because sales of X are my livelihood'.

Of course the owner has the right to say that. But that doesn't mean
he has the right to actually prevent you from obtaining a copy from
another source. Currently, he can *legally* prevent you from doing so.
That doesn't mean he's behaving morally in doing so.

<There are many positions that can be held wherein such property rights are
<given over to some other party (the State, the People). But in all cases, the
<original creator must be *paid* in some way for the transfer of these rights.

Oh, yeah, like RMS got paid for GNU emacs, right?

<If this is not done, society is left without all forms of professional
<intellectual creation vocation. This would be rather serious!

I don't think it would be nearly as bad as you think. Let's look at
the list of people you think we'd loose:

< - The obvious: songwriters, authors, artists, programmers, etc.
< - Money market-watchers (contents of newsletters)
< - Market research firms (contents of research reports)
< - Product testing companies (test reports)
< - Architects (blueprints, building designs, etc)
< - Professional cooks (recipes in cookbooks, etc)

You didn't break things down into nice categories, so I'm going to re-arrange
things:

- artists, including songwriters, authers (fiction), and others

Many of these people don't expect to make a living on the artwork they do. How many artists do you know of whose works are now selling for fortunes scraped by for most of their life, and died penniless?

- toolsmiths: programmers, architects, research firms & product testing

Except for programmers, most of these don't make money on sales of multitudes of copies. They make money by contracting out to right the original product, and then just hand the report (and copyrights) over to whoever paid them to produce it. Many programmers work on the same scheme.

- Howto book (cookbooks, etc), and similar mass market people.

These people will have more problems. But currently, the cost of copying a book is more than the cost of the paperback. People trying to sell overpriced hard & tradebacks would probably loose sales. But that doesn't kill the works of the authers, only restricts the format they can publish in slightly. And there'll still be a market for hardbacks & tradebacks in the presence of paperbacks & slightly more expensive copying. After all, there is now.

- money market watchers

These people tend to sell to a small, select audience by subscription (overpriced, at that). Adding a license agreement to the affet that you recieve the newsletter under the condition that you not give it to anyone else is a minor matter.

Basically, the only thing lack of a copyright law kills is things produced explicitly in hopes of making money by selling lots of copies of something. My reasons for claiming why a minority of software written fills that bill have already been posted. I believe the same about everything else, with the possible exception of mass-market books. And loss of coypright laws won't hurt mass-market paperbacks worth noticing.

On the other hand, copyright laws tend to restrict the free flow of information. This causes duplicated work, lost work, and numerous other things generally considered bad for society.

[This is being posted far & wide, as I have been asked to do so.
Followups have been pointed to comp.sys.misc.]

Here, as promised, is a description of what you need to do to shareware and freeware so that the law will be on your side about what people do - and don't do - with it. I consider most of it is common sense, but "legal" and "common sense" seem to have little do with each other, so some people might find it usefull.

<mike

-------------------- document begins here --------------------

This document

Copyright 1987 by Mike Meyer
All Rights Reserved

The whole of the document may be freely redistributed. Parts may be freely redistributed so long as the disclaimer and the list of the evils of shareware are included with those parts.

The following presents some simple guidelines for what should - and shouldn't - be present in a shareware product so that the authors may be able to use the law to extract money from people who use, but do not pay for, their product. There is also a discussion of things you might and might not want to include in freeware. These guidelines are based on a study of the copyright laws, and discussions with lawyers. As is usual for software, the laws are still unclear, and there has not been a precedent covering what is and isn't correct. The following disclaimer is needed for that, as well as to cover for my own fallability.

Disclaimer: These guidelines not guaranteed to be correct.
Follow them at your own risk.

When in doubt, consult a lawyer. You'll pay for it, but you have some hope of compensation should you get bad advice.

I believe implicitly that knowledge should be shared, and I possess knowledge that it seems many will find useful. Therefore, I'm going to give guidelines on what to do to shareware products so that you have a hope of extracting funds from non-registered users in a court of law. However, I'm going to insist you listen to the things I consider evil about shareware, and ask that you consider making your package publicly available instead of shareware.

Among the evils of shareware are:
1) It violates the hacker ethic.
2) It uses channels of distribution originally
intended for freeware, without compensation to
or permission of the people who run those
channels.
3) It uses intimidation to coerce money from people.
4) It entices them to break the law.

You are also going to have to listen to my lecture on what public domain really means. Why don't we start by defining that?

Public domain, contrary to an apparently popular believe, means that anyone who has a copy may do whatever they wish with that copy. Including put their name and copyright on it, and sell it as a commercial product. By placing something in the public domain, you've given it to whoever wants it to do whatever they wish with it.

Next obvious question: How do you place something in the public domain? Well, the easiest and fastest way is to publish something with the words "This is in the public domain" prominently displayed. Doing that negates any copyright notice you may have on it. The second way is to publish something without putting a valid copyright notice on it. This isn't as fast, as there are provisions in the law allowing for the accidental publication of things that should have had a copyright, but don't.

Note that a statement "this is in the public domain, not for commercial use" is self-contradictory. The document in question is in the public domain, and available for commercial use.

As an aside, in the context of shareware and freeware, "publish" means making available to others - uploading to a BBS, posting to USENet, or sending to a software library would all constitute publishing.

At this point, the first guideline should be obvious:

Put a valid copyright notice where it will be seen.

Of course, you need to know what a valid copyright notice is. The one at the top of this document is valid. In general, you want, on a line by itself, the word "copyright", the year of publication, and your name. If you can produce it, the copyright symbol (circle-c) will do instead of the word "copyright". However, the ASCII-ism "(c)" is not a valid replacement for that.

In most of the countries that agree to the international copyright laws, that is sufficient. Some, however, require you to explicitly state what rights you reserve. For that reason, the second line "All Rights Reserved" should be added if you plan, or expect, distribution outside the United States.

These should be placed where they will be seen. If you have a title screen, put them there. Near the beginning of any manual you provide

is another good choice. Printing them on a standard output stream is a possibility, but will give filters headaches.

To give those of you a who are considering doing the right thing and publishing your product as freeware instead of shareware some extra options, I'll point out that after the copyright notice you can place a notice allowing redistribution under specific conditions. A common thing to see here is "This code may be freely redistributed so long as it is not included as part of any commercial product" or words to that affect. The GNU copyright notice is probably the best example of this. They wished that anyone who wanted to use their software should be able to, yet that nobody be able to make money off it by selling it, that there not be multiple version, and that they not be held liable for it's correct operation.

If you still want to make money off it, instead of donating it to the good of society, you need one more thing - a license agreement. This should be as explicit as possible. Asking for money doesn't do it - if you merely ask, you're begging. You have no legal right to expect money. So avoid the words "please," "donate," "grateful," and the like.

The best thing to do is to have a specific license agreement that must be printed, signed and returned with a check. Then near the copyright notice put a notice stating something like "Use of this product without returning the license agreement and registration fee is a crime." Except, the more specific you can be, the better. Instead of just saying "Use", say "Use more than 5 times," or "Use for more than 2 weeks."

Should the license agreement seem to much to add to the product, just place a notice like "Use of this product without registration by sending $# to <whoever you are> is a crime." Once again, be specific - give a number of trial uses, or the length of a trial period.

So the second basic guideline is:

Be as explicit and fascist as possible about licensing.

I have purposefully left the description of a "shareware license agreement" off. It's up to the shareware authors to decide what they want to put there; I've described how you can get a good chance of actually having it enforced. I'd ask for a shareware author to contribute a sample, but that seems pointless.

That's really all that's needed - a valid copyright, and explicit and fascist conditions on usage. While this doesn't guarantee that you'll be able to extract money in a court, it gives you the best chance possible without going through commercial channels.

Of course, corrections to any of the suggestions above will be gratefully accepted. Suggested improvements in the document as a whole would also be appreciated.

Recommended. I got my 1040ST from them about a year ago, and had absolutely no problem. It is warranteed, the price was great, and it got here promptly. Their support is also decent. An unexpected bonus: I ended up getting a 1040STfm.

It's not really unsolicited -- the fact that your machine carries the sources and binary groups, the fact that you invoke "rn" or another news reader, the fact that you type "s filename" ... all of these are VERY comparable to downloading from a BBS.

But this discussion is MOOT because shareware does not usually solicit contributions for POSSESSION but for USE, and use never is involuntary or unsolicited.

1444. Re: Absoft Fortran...

Newsgroup: comp.sys.atari.st
Date: 1988-01-30 15:20:11 UTC
From: btb@ncoast.UUCP
Message-ID: <7146@ncoast.UUCP>
Source record: 254844

about fortran on the ST...
i got some info from absoft that was a little more informative
about its availability on the ST, but the main point is that absoft fortran
supports the ST much the same way that absoft fortran works with the
macintosh (i used absoft fortran on a mac back in 1984.)... absoft supplies
one single hook into the operating system calls through which all gem
stuff passes, etc. absoft fortran on the mac was a very decent system,
and having the inside mac docs available (at the time) and the relatively
friendly (compared to GEM) mac toolbox, making toolbox calls wasn't too
painful, but on the st (i have mark williams C) i think that it is much
more difficult to access GEM in this way.
my one complaint about the info from absoft is that they charge
a nominal fee ($100/yr) for a license (?) to distribute their runtime
library with the applications that you develop.
another fortran that looks somewhat more practical (to me) is
made by PECAN software in Brooklyn New York... they supply a turtlegraphics
library for simple graphics applications AND they make their fortran
with turtlegraphics available for a wide variety of machines including
ibm pc's, pdp's, amiga's, etc. (actually, it sounds almost too good to
be true, and all of this i've taken only from their literature (which looks
very professional).) this should mean that one could develop applications
using their turtlegraphics on an ST, and then be able to very easily
port the application to other machines just by recompiling it on the
target system with their compiler for that system. even microsoft doesn't
supply a decent graphics library for their languages (except the new
graphics primitives in msc 5.0). pecan's phone number is:
(718)-851-3100. they look like an american extension of an english
software company.

I understand that people have been having trouble with Personal Pascal's editor when they try to edit programs on their MEGAs. While this may be of dubious value, I can tell you that the early versions of Personal Pascal work fine on the MEGAs. I have v1.11 that I bought a while back and never quite got around to upgrading. Its editor works fine on my MEGA2, and everything works fine when I ramdisk.
Hope this helps!

To set the seek rate on your floppies _after_ bootup [grin], you must
use unsupported system storage locations. They are:

Drive 0 [word] Old roms: $A08 Blit roms: $A4E
Drive 1 [word] Old roms: $A0C Blit roms: $A52

The flags are the same as for the system seek rate stored in ROM.

> return for their efforts, and aren't satisfied with fame or esteem or whatever
> else.

Sure they are. People want capital back. Capital is usually considered
money, but really it's anything that you value or can trade for something
you value. Money is a handy token for capital, but fame, self esteem,
a nicer place to live, and good sex are just as appropriate. Physical plant
is also capital (something even the Soviets have to deal with... when they
pretend it isn't we get things like Chernobyl)... but I'm digressing.

People who don't understand capitalism are condemned to reinvent it -- poorly.

But did you 'subscribe' to this group on Usenet knowing that you would get shareware in it? I'd bet so....

If this is the case, you're not getting anything 'unsolicited'. And in any event, even with Usenet, it takes *work* and *time* to get the software on your system. (uudecode and file transfer aren't automatic!)

Unsolicited? If it showed up on your system without warning or notice, it would be. But the act of converting/downloading the stuff certainly is an act which could be considered 'solicitation' of the software... you ARE trying to receive it; it doesn't "just arrive".

From: crash@calgary.UUCP
Message-ID: <1324@vaxb.calgary.UUCP>
Source record: 254850

Hi,

Well the external ram disk project is moving ahead very well. I expect
chips back from fab at the begining of March.

If it works, Then the chip and a pc board will be for sale initially.
I haven't got any time for marketing and such until I finally get school
finnished! Thus, only people who can work a solder iron will want
the Ram Disk. When I do get time, I figure out how to sell them as packaged
units.

As I keep promising... I'll put up some info about the chip, kit etc. soon
(that is, soon as I type it !)

If your interested in one of the chip and board versions send me mail.
If you already have then I've still got it. i don't know how many working chips
I'll have, but I'm told at least 20. Requests will be handled first come
first serve.

Glen

P.S. I'd be interested in just selling the chips to someone and they could
market packaged units or something like that.

I have found that Tim Oren's "ST PRO GEM" articles are probably the BEST way to get a grasp of how GEM works, if that is what you are interested in. They are available in the U.S. on Compuserve, in Antic Magazines Atari ST SIG (I think). Do to the copyright on the columns, I cannot post the columns here, but I can mail them to you on disk. (The columns all say "Permission to copy is granted as long as this message remains intact", or words to that order. I once asked Antic if I could post them on BIX, and they said it would violate their agreement with Compuserve.)

Anyhow, I have the columns on three 720K disks: One contains the original columns, one contains the columns in first word format, and one contains the C source that accompanies the columns. Say $10 for disks and postage, U.S. and Canada. Try to find them locally, if you can't, send mail and I'll send them to you.

In accord to Mike copying restrictions:

>The whole of the document may be freely redistributed. Parts may be
>freely redistributed so long as the disclaimer and the list of the
>evils of shareware are included with those parts.

You will find the above at the end of my reply.

After reading the message, I was kind of puzzled. Mike, a known "hater" of shareware, giving guidelines on how to protect shareware and help make money off it? Strange! But after reading the licensing notice he suggests including in the shareware program:

>"Use of this product without returning the license agreement and registration
>fee is a crime."

and

> Be as explicit and fascist as possible about licensing.

I came to the conclusion that he just wants to have some stupid shareware author to exactly follow one of his "shareware evils":

> 3) It uses intimidation to coerce money from people.

But again, let's not process Mike's intentions (I apologize in advance, Mike, if I misinterpreted), and go to the details.

>The guidelines are based on a study of the copyright laws, and discussions]
>with lawyers. As is usual for software, the laws are still unclear, and
>there has not been a precedent covering what is and isn't correct.
>The fact that there is no precedent I believe implicitly that knowledge
>should be shared, and I possess knowledge that it seems many will find useful.

Part of your document shows knowledge, part just shows guessing bordering on misinformation (my personal opinion, which I'll try to substantiate with my reply).

>Therefore, I'm going to
>give guidelines on what to do to shareware products so that you have a
>hope of extracting funds from non-registered users in a court of law.

>You are also going to have to listen to my lecture on what public
>domain really means. Why don't we start by defining that?

Well done run down on the public domain/copyrighted/restricted issues.

>Note that a statement "this is in the public domain, not for
>commercial use" is self-contradictory. The document in question is in
>the public domain, and available for commercial use.

I just downloaded two programs from comp.sources.amiga with that STUPID notice.
Hey, you guys that wrote that. I can tell you right now that I feel free to
do anything with it. If I find it useful I will use it in a commercial product
of mine, and will definitely copyright the resulting code with MY name on it.
And you won't be able to do anything about it! Got it! :-)

>As an aside, in the context of shareware and freeware, "publish" means
>making available to others - uploading to a BBS, posting to USENet, or
>sending to a software library would all constitute publishing.

This is very important. From that date the author has 3-months to register
with the Copyright Office to be able to subsequently claim statutory and not
just "actual" damages.

> Of course, you need to know what a valid copyright notice is.

All is well on this. If one wants more, get the "Circular R1 -- Copyright
Basics" from the Copyright Office, Library of Congress, Washington, D.C. 20559.

>I'll point out that after the copyright notice you can place
>a notice allowing redistribution under specific conditions. A common
>thing to see here is "This code may be freely redistributed so long as
>it is not included as part of any commercial product" or words to that
>affect.

This is definitely enforceable by the courts (More at the end of my message).

>If you still want to make money off it, instead of donating it to the
>good of society, you need one more thing - a license agreement.

Here is where the sticky part starts. The copyright issues are ended,
and Mike goes into the "Licensing Agreements" issues, a MUCH different
subject.

>The best thing to do is to have a specific license agreement that must
>be printed, signed and returned with a check.

This is still OK. "Licensing Agreements" should be signed by BOTH parties
that are included in the agreement. This is usually the case for mainframe
and minicomputer software. BEFORE getting the software, the purchaser has to
sign the agreement, and return it with the proper payment.

With microcomputer software the story is different. Given the large quantities
and the different distribution channels, almost all publishers
now use the "Shrink-wrap licensing agreement". The agreement is either
printed on the outside of the shrink-wrapped package or the diskettes are
inside a sealed envelope. One has to PHYSICALLY break some type of seal to
USE the program, and to break the seal, he/she MUST have read the licensing
agreement. Most agreements say something like this:

"Breaking the seal on the envelope indicates that you accept this agreement and will abide by it. If you do not agree with the license, return the complete software product to the dealer where purchased". Usual agreements require an limited amount of backupus (if any) and use on a limited number (usually 1) of cpus at any one time.

Note that the "Shrink-Wrap Licensing Agreement" has never been tried in courts, and therefore it is not clear whether it will stand or not. Moreover, not being connected with any Federal law, each state could decide in his/her own way.

>Then near the copyright
>notice put a notice stating something like "Use of this product
>without returning the license agreement and registration fee is a
>crime."
>Should the license agreement seem to much to add to the product, just
>place a notice like "Use of this product without registration by
>sending $# to <whoever you are> is a crime." Once again, be specific -
>give a number of trial uses, or the length of a trial period.

This is where Mike's arguments die. He suggests a kind of even looser "licensing agreement" that does not include the "break-seal or open-shrink-wrap" action. Note that the "shrink-wrap" agreement is based on the fact that one opens the seal AFTER having read the agreement, and BEFORE using the product. The breaking of the seal is also an undeniably PHYSICAL action.

With shareware that is not possible, unless one can prove that whoever gets the software sees the "shareware license agreement" BEFORE downloading it from a BBS, getting it from a friend, or by other means.

Even including the "shareware licensing agreement" in a LICENSE file on a BBS won't do any good, unless the sysop enforces the rule that you have to download the licence BEFORE you download the program; clearly unenforceable with current BBS software.

Also including the LICENSE file as part of a library ARC file that contains the executable won't do any good, since NOBODY will be able to prove that I read the agremeent BEFORE I use the program.

Thirdly, flashing the licensing agreement each time the program is started is also useless, since that is done AFTER you got the program, not BEFORE. Therefore, you are in NO obligation to follow it.

Considering the questions on the legality of the "shrink-wrap" licensing agreement, ther is NO chance that the even looser "shareware agreement" that Mike is suggesting will help anybody to recover any money at all.

Most shareware authors for the IBM PC have clearly understood this, and try to make their money by providing "extras" with the "registration" of the program, which usually includes a new BETTER version of the program and printed documentation (ZCOMM/Pro-Yam, PC-FILE, PC-TALK III are examples of this). Another possibility is "selling" technical support (I believe ButtonWare does this).

>Of course, corrections to any of the suggestions above will be
>gratefully accepted. Suggested improvements in the document as a whole
>would also be appreciated.

You've got them. My point is that your proposed "shareware license" is basically useless from a legal standpoint. And I did not even consider the enforceability of such an agreement.

Going back to the Copyright issues, this is an area where laws are clearer and there are precedents. One issue, for example, concerns a variety of outlets that repackage "shareware", putting multiple programs on the same disk, and SELLING the result. If the shareware software is properly copyrighted and registered, and includes proper restrictions, one can easily sue these companies, stop them from distributing "illegally" your software, and possibly recover court-awarded damages. This has been done.

Even if I do not agree with some of Mike's arguments, I do commend him for raising the issues.

-- Marco Papa

As requested, here they are:

> Disclaimer: These guidelines not guaranteed to be correct.
> Follow them at your own risk.

> Among the evils of shareware are:
> 1) It violates the hacker ethic.
> 2) It uses channels of distribution originally
> intended for freeware, without compensation to
> or permission of the people who run those
> channels.
> 3) It uses intimidation to coerce money from people.
> 4) It entices them to break the law.

{Greetings and salutations, oh bug eater!]

Hi. I just acquired a 1040ST, and when I am not chasing my
housemates off of it (as they play Dungeon Master!), I spend time
trying to hook up my Apple ImageWriter to it. I have the cable, no problem.
But I can't make some of the software that I have (especially Publishing Partner)
to talk to the printer. Is there much in the way of ST stuff that'll drive a

Any help that y'all can offer will be appreciated. Thanks.

Yes, if a Developer's Kit for RTX was available for a small fee (~$40),
and was _well_ written and _informative_, it would make lots of money for
Dave. Just learn from Atari's mistakes :-)

Anybody think it would be possible to install a trap handler to intercept
the calls to output to the printer and send the output to a file? Perhaps
a desk accessory (Yet Another DA!) like Tom Hudson's Hard Disk Write Protect
DA? There are quite a few programs out there that do not have the option to
print to a file...and since I have an FX-80 and the school has a laser
printer, I usually try to print to a file and upload to the school's
system (The laser printer emulates an Epson in any case).

Any ideas?

> Simon's reorg program helps a bit, but ...
> Also, if good is it part of a wider package or on sale as is?

It helps on reading directories, not on creating or writing ...

My suggestion is: Do a diskcheck with dlii. If all is well, write a
file to that partition which fills up the partition to maybe %5 free.
Run dlii again and reorg. If that big file was written to the root
directory, it will be fairly close to the beginning of the partition.
Then remove the big file. All the free space is now at the beginning of
the partition.

AS ALWAYS: BACKUP YOUR DISK BEFORE USING A PROGRAM LIKE RE-ORG!!!!!

Disclaimer: This is my work-around of what Michtron's Tune-up! does.
I do not have the money to buy it so I created my own
method of doing the same thing.

guess they don't have quick printers in Richardson Texas! Their last
manual was just laser printed masters. The real problem, is that they aren't
done with the program yet. This isn't something that is bad, it is good. I
would rather have them hold off on the release of a buggy product, than to let
it go as it is now. The lastest Beta Version works fine, but still has some
quirks. The good thing is, they won't have to wait for the manuals *if* they
are being printed now!

and a lot more things which we probably all agree are correct..
....
>Even with all this planning, the XT's still beat my ST. Are you listening,
>Neil? Your people are crying out for help ;-).
As people that have been following the net for the last two years have
noticed, the only positive action that Atari has ever taken about GEMDOS
bugs was the famous 'We're working on it!' from Neil Harris, concerning
the 40-folder problem nearly exactly two years ago. Since then Atari has
fixed problems in the BIOS and XBIOS and even some bugs in GEM, but
none of the minor or major GEMDOS bugs have been fixed. Why?
Well there were two possible ways Atari could have improved GEMDOS
since they started noticing the bugs (which as far as I know, happened
when they started shipping hard disks to developers (late 85)):

1) fix the bugs inhouse, which would have been pretty easy
for most of them (in fact for most problems they wouldn't have to
have done it themselves: more than one person in Germany
have actually rebuilt the C-Source of GEMDOS by diassembling
the ROM's (one of them has actually published a book with
the listing) and have repeatedly pointed out how to fix
the bugs to Atari (most seem to be results of typos)). Only
solving the '40-folder' problem would have needed some rewriting
of the OS since this is a design problem of the internal
memory management of GEMDOS.

2) Get the fixed GEMDOS from DRI, that a fixed version of GEMDOS
exists inside DRI has been rumoured since the beginning of last
year, one report even quoted somebody from DRI saying that they
had given it to Atari.....

So what's Atari's motivation not do to anything about GEMDOS (except
spreading rumours that they are working on a completely new OS (and even
if they are it must have very low priority (just one person working on it)))?
Well it costs money and if you have such a good scrapegoat as DRI,
why bother? Plus, all the GEMDOS problems have not hurt sales in Europe
(specially in the German speaking part), this is partially due to Atari
suppressing the information (the 40 folder bug was left out of the
German SH204 manual and only became widespread knowledge around Summer 87),
partially to the computer press not being critical enough about what
Atari Germany told them (remember the sentence 'The development of GEMDOS
is finished!' by Mr. Stumpf).

Now the only reason I bothered to write this is the astounding insolence, that the same company that doesn't even bothers to support the OS on it's major line of computers, is actually intending to be selling 4 (FOUR!) different lines of computers, plus 4 different operating systems, plus 4 different window/graphic packages in 1988! Atari must really think that we are stupid!

> of the status of the code is not usually possible. Ah well, back to the
> flames.

Obviously you don't frequent the BBS's and computer clubs that I do. The closest to ""documentation"" that these small-time operations present is a listing of the disk directory (piped to printer, of course). Now, if you see a file named "expr34.exe", can you tell that it's shareware? Ya download it (or copy it), and take your chances (with hard drive out of the system, of course!).

Sorry, won't cut it. If your argument is that these programs were "clearly marked", then don't distribute them through channels that eliminate this "clearly marked" status (i.e. BBS's and clubs). Whereupon you just eliminated the whole argument for shareware (the wide distribution).

Actually, there's something akin to shareware that might be even more popular in the future: Teaserware. An example is the "Express" word processor for CP/M. They have a teaser out, that implements most of the features of the full word processor, and is useful, to boot (certainly beats VDE, VDO, and any other PD CP/M word processor that I've seen). If I used CP/M much, I'd probably send in my $40 or whatever for the complete program and manual. On the other hand, I wouldn't know that these people existed if they'd gone the usual distribution route (is there even a magazine for CP/M anymore?!). Alas, I doubt that many other programmers would do the same... they'd probably just release a silly demo program that was useless for doing anything but advertising the full-fledged program. Instead of what the authors of Express did, releasing an early version of the program into the copylefted domain, quite useful in what it does (basic text editing).

> damages, which are decided in court and have NO set limit.

About 6 months ago, I looked at the appropriate part of the U.S. Code.
"actual" damages apparently are based upon how much the publisher would have
recieved by actually selling the copyrighted material. Statutory damages DO
have a set limit: $10,000 per occurance, with a $50,000 cap for blatant
offenses. Or some such numbers. Note that these are a PER INCIDENT fine (there
is a minimum fine, also). If you have a company that made 1,000 copies of
Lotus 1-2-3, that company may be liable for $10,000,000 in fines (as vs. the
$500,000 they'd be assessed in "actual" damages). Also note that there are two
routes: Civil (you file suite against the infringer), and criminal (a U.S.
prosecuter asks for indictment). There's also other assorted goodies that the
judge can order: Siezure of all involved equipment and goods, for example.

Conclusion: The copyright law may be one of the laughs of the century, but if
someone finds a big offender, we're talking big bucks.

Caveats: My photocopies of the relevant sections are buried in boxes from when
we moved, so you're spared the long & gory details. Needless to say, REGISTER
the program, if you want to protect the various rights associated with
copyright...

I'll agree that the 'Concise ref. Guide' is a good book.
But recently I have read the book 'ATARI ST Profibuch' from (german) SYBEX (isbn 3-88745-501-0). It's the ultimate book, everything I have on information was in about 4 books, but now I only have to use this one.

The contents:

The operating system of the ST:
BIOS, XBIOS, GEMDOS, VDI, AES, Systemvariables.

The hardware of the ST:
Complete description of all the hardware (including the BLITTER)

The version wich I have is written in German, but perhaps there's an English version somewhere.

PS. It's 760 !! pages for about $35.

1466. Re: Mega vs 1040ST

>For about a week Atari Holland is shipping the blitters to the -old- users.
>But the blitter does not give the ZAPPP-speed you may expect. But it's free.

There's a lot of misunderstanding about this above statement. The -old- users ar
e the users who have bought a MEGA without blitter and not the 520/260/1040 user
s.

It's free means that there isn't a way to buy a MEGA without a blitter. You'll p
ay for the blitter but you'll get it later. When it's ariving you don't have to
pay anymore.

So, that's justified.

>every few months instead of every few decades.")

>Andrew Weaver, OSU College of Business weaver@tut.cis.ohio-state.edu

I must disagree with Andrew's point about putting the OS back on disk so we can get updates every few months. As much as I like the idea of frequent updates, I absolutely detest having to waste mongo megabytes just getting the stupid machine to boot. I work with Macs a lot, I really get frustrated when I can't even copy files between two disks because I have ONLY two floppies and neither of the disks I'm using has a system on it. I really like the way the ST boots without the system files on disk; that way you only waste DA space on the disk. It also speeds boot time a lot. Admittedly, if you have a hard disk it won't make a major difference, but I doubt most people do. Perhaps Atari could do something really neat and use the cartridge port for something, instead of just letting it sit off the side of the computer, as it does now. I'm not sure of any details, but it seems the cartridge port is the way to go as far as a compromise between ROMS and disks goes. After all, you can get those Atari 2600 cartridges for a few bucks now - and I can't believe that the price of making a cartridge is that much more expensive than making and copying a disk. And what if it is? Maybe the cartridges would become more popular and might actually be useful in the future (aside from David Small's Magic Sac, of course).

1469. BITNET redistributions and USENET Gateways (or Why I Hate BITNET)

Newsgroup: comp.sys.atari.st
Date: 1988-01-31 22:59:46 UTC
From: fair@ucbarpa.berkeley.edu
Message-ID: <22802@ucbvax.BERKELEY.EDU>
Source record: 254769
Cross-posted to: comp.sys.atari.st,news.misc

Lately in comp.sys.atari.st there has been a flurry of bounced digests and other cruft being posted by my gateway from the bowels of BITNET. Sorry that I took so long to respond folks, but I don't read comp.sys.atari.st and I didn't know about it until the middle of last week.

Quick explanation: comp.sys.atari.st is bi-directionally gatewayed to INFO-ATARI16@SCORE.STANFORD.EDU. Among the other addresses on this list are redistribution points for BITNET. Unfortunately, someone on BITNET is not doing his/her header hacking right, and when delivery fails, the digests get bounced back to the whole list, instead of to the responsible administrator. Ah, if they'd only convert to netnews, we wouldn't have this problem...

Fortunately, my gateway can filter stuff, and now that I am aware that this is happening, there is a filter in place to stop it from ever reaching those of us fortunate to be on USENET. I have also posted cancel control messages for those errant articles, so they will be removed from your disk as soon as the control messages arrive on your system.

The responsible BITNET site, so far as I am able to determine is CANADA01, and as soon as I know who the site contact is, I'll post his/her address here as a followup to this article to let you all know who to bitch at. Failing that, you can complain to INFO-ATARI16-REQUEST@SCORE.STANFORD.EDU, which is the address of the ARPANET mailing list coordinator.

keeper of the ucbvax USENET gateway,

Erik E. Fair ucbvax!fair fair@ucbarpa.berkeley.edu

P.S. there is a special place in purgatory for the people responsible for BITNET's so-called mail system.

Before we're innundated with gobs of flames, I'd like to point
out that Bill Westfield (he's the chap who puts the digests together)
has added a "SENDER" field to the outgoing digests, in the hope that
the errant BITNET mailer(s) will bounce mail back to the address in
the SENDER field, and not to the name in the "FROM" field. The SENDER
field is set to "info-atari-request" so that we'll get the bounced
digests and take action. The "FROM" field remains "info-atari", so that
BITNET folks who use the REPLY function to send notes to info-atari will be
able to do so without swamping the "request" address with mail that
should go to the list. Of course, all this assumes some sort of
rational behaviour on the part of the BITNET mailers...

>P.S. there is a special place in purgatory for the people

I have to agree with most comments that a lot of shareware are hardly worth the diskette space and might be considered for freeware. I have also seen a few commercial products that fit that category also :-).

The perfect exception to the rule is however, UNITERM, this is the best product that I have seen ever in the freeware, shareware world. It is also the best terminal program that I have ever seen. Including the commercial products in this area. Some have more a few more whiz-bang features. But none are more functionally complete, and this makes it (in my opinion) the perfect interface to your favorite mainframe. I do know lots of people who will quickly disagree with me, but they are not mainframe users, the only interfacing required is with BBS's and other users. The other programs that I have tried at their homes when they have challenged me with their perfect term program have all failed miserably in the emulation modes. Uniterm works perfectly without a hitch!

Anyway... I just wanted to say thanks to Simon Poole for a great product, and to give a "this one's great too!" addition to the list of public domain and somewhat-public domain software.

This is my first post so please bear with me. I have to agree with the points Adam Engst brought up. Since the cartridge port was included on the ST, I would like to see more software produced in cartridge format. Personally I believe there may also be a great market out there for someone who could come up with a better operating system (Not that there are any flaws in GEM 8-)

> What situation would cause Mediach() to return "maybe"?
>
> Karl Rowley

In one of the recent conferences on BIX, this was brought up. As I recall, the answer was that Mediach() returns maybe if the disk is write protected.

The ST uses the write protect line to sense disk changes. If there is no disk in the drive, the drive reports "protected". If there is a disk in the drive, then the drive reports whatever the disk is set for. So, the ST can accurately sense the changing of writeable disks, but not protected disks. So, if it reads from a protected disk, it sets the flag to maybe as soon as the drive motor times out, because it really doesn't know.

From: ames!scubed!sdcsvax!pnet01.cts.com!sreeb (Ed Beers)
To: atari!neil
Subject: Re: developers kit
Status: R

I keep hearing persistant rumors that a new version of the developers kit with
Mark Williams C included will soon be available. Any truth to this. If not,
any chance you guys will unbundle the documantation from the software?

UUCP: {cbosgd hplabs!hp-sdd sdcsvax nosc}!crash!pnet01!sreeb
ARPA: crash!pnet01!sreeb@nosc.mil
INET: sreeb@pnet01.cts.com

Answer:

The current developer kit includes Mark WIlliams C for the $300 price, which
includes the Atari documentation and technical support.

The documentation is available separately for $100. Alcyon C is available
for $20.

Mine's (and all the others around here) been flawless. I think it has to do with making regular backups; if you back up the disk once a week, you will never have problems. On the other hand, if you don't make backups, you can expect trouble. I believe this is some corollary to Murphy's Law :-/.

1481. small assesment of some formaters

Newsgroup: comp.sys.atari.st
Date: 1988-02-01 19:18:29 UTC
From: gpm@dukempd.UUCP
Message-ID: <439@dukempd.UUCP>
Source record: 254781

Recently I aquired four formaters: the Atari standard, the Twister, format11 and DCformat. All but the Atari came over the net and I would like to thank the people who posted them- even though I can't remember the names. Over dinner one evening I deceided to compare the read from and write to times of these four formaters. I collected this information using the time command of the Gulam shell, so the times are in units of 5 millisecond clock ticks. The Gulam command df reports the disk sizes. The list is ordered as to increasing size of formatted disk.

formater	size(kb)	write to	read from
Atari	728	12,354	7,586
Twister	810	5,470	5,112
DCformat	830	5,547	4,864
format11	925	14,933	8,421

Reformatting the same disk on each trial, I moved 220 kb of files (programs, archives, 1st Word documents et al) from a ram disk d: to disk drive a: using the Gulam sequence "time mv *.* a:". This gave the "write to" time. I then moved all the files back to the ram disk with "time mv a:*.* d:". This gave the "read from" timing. All these operations were moves ie copy and delete, so the more common straight copy will be faster: this is a comparison not an absolute performance test.

As most of us already know the Atari standard formater produces small, slow disks. Format11 makes a big but enormously slow disk; although, it is so large as to be a suitable archival material, but not for everyday use. I find Twister and DCformat very close in performance and good for everyday use. I personally use DCformat for its versitiliy; but only after haveing used and been satisfied with Twister for many months. The DCformatter is more versitile, and this has swayed me to its side. I should mention that I used DCfomatter in its 82 track, 10 sector/track fast mode with the write verify turned off; the other three have only one way to use them.

Disclaimer: I neither know nor understand anyone who writes or distributes formaters, these four included.

P.S. I'd still like to hear from someone about my desire to find a resizeable and reset survivabl ram disk.

At least tell me why it's hard to do. I got no responce
to an earily inquiry except for requests to pass any
information along.

Has anybody seen or heard anything about the new HP DeskJet Laser Quality printer? I just read an article on it in the newspaper, but it didn't give too many specifics. It did say that it was $995, 300 dots per inch, two pages per minute, uses a replacable ink jet head ($18.95) thats good for about 600 pages, it uses regular paper. The article also said that it was HP and IBM compatible. OK, but what kind of printer driver would I need? Is it postscript compatible or what? If anyone has any more information on this new product please let me know.

Here is a more international view on copyrighting software, as I understand it. I hold a Danish master degree in legislate law, but I am no expert on copyrights. I once spoke to a Danish expert on the issue and this is what I remember from that talk. Usual disclaimers.

Copyrighting in the USA is something special, as USA has not ratified the Berner convention, as most of the European countries have, and Canada has done it too. As software put one EUnet/Usenet is spread all over the network in a couple of days, you can consider it published in Berner convention countries, and thus international copyright laws apply to every single piece of software published on the net.

According to the Berner convention, it is not neccesary to state "Copyright" etc on the work, if the "work" is of sufficient "height" with respect to originality, it automatically enjoys copyright protection. But it does improve your chances proving that it is your software if you have put a copyright notice on it. And putting a copyright notice is a good idea, if you also publish it in the USA.

The Berner convention has no such thing as "public domain", and if you have put something in the public domain and later regret it, well you can do so in Berner convention countries. You are able to give rights away like saying "Copyright by Frobozz 1988. Permission to copy is granted as long as ...", so this is like discussed elsewhere.

One special thing is that it is legal to copy any copyrighted material if this is for *private* use. This covers music played on the radio which is tapped on your tape recorder, and it also covers software which is published on the net and thus governed by copyright rules. Putting out sentences about "crime" is thus not fully true in Berner convention countries.

Please note carefully: THIS IS NOT AN ANTI-MAC FLAME!

We wonder about the reasons software and hardware prices are high? In
an article from comp.sys.mac, rock@sun.UUCP writes about MacWorld Expo:

-The attendants were dressed up like space folk from the TV series "V".
-There was a videotaped 9 minute tour by Leonard Nimoy
-a slick young card shark right out of "Guys and Dolls".
-a guy and gal doing a song and dance take-off of "Entertainment Tonight"
-they gave out top hats
-holding drawings for lobster dinner for two, Federal Expressed in from
Legal Seafood of Boston.
-a drawing for a LazerJet printer
-a drawing from Apple.
-a laser light show on the ceiling.

Somehow, I think a little less expensive glitz might help a bit...

1487. <Control> C and autostarting GEM programs

Newsgroup: comp.sys.atari.st
Date: 1988-02-02 01:05:40 UTC
From: Gribnif@UMass.BITNET
Message-ID: <880201194539737.AETG@Mars.UCC.UMass.EDU>
Source record: 254787

Greetings,
I realize there have probably been atleast two buzillion (okay, I'm exaggerating, one buzillion) questions relating to TOS' handling of the <Control> C key and ways of disabling it, but I'm sure we could all use a refresher course by now... :-)
I have found that using the XBIOS (or are they BIOS??) functions Cconws/Cconout to send information to the console is actually quite nice for the application I am writing, since they allow the user to use <Control> Q and <Control> S for flow control of the data on the screen (whereas the "raw" output functions beginning with "B" do not.) The problem is that as soon as the user enters a <Control> C the program is immediately terminated with a status -32. Not nice.
So it all boils down to this: has anyone found a LEGAL way (short of redefining the keyboard, assuming TOS is looking for the ASCII and not the scan code--redefining it would be inefficient for me anyway) of disabling or trapping the key so that the program is not terminated? Moshe?
Second of all I would like to know how programs like GEMSTART work and if they can, in fact, work with the new ROMs without modification (I have heard that the original GEMSTART won't work with the new ROMs.)
If you want to try something rather humorous, write a DA that Pexec's a GEM program as soon as it runs. The application runs normally, puts up its menu bar and all, but as soon as it does an evnt_multi the desktop magically takes-over control once again which, of course, leads to several bombs if you get tired of watching disk drive windows pop up from nowhere when you click on the desktop and decide to select a menu item.
Thanks in advance!

I would like to put in my vote for a public domain version of the MT C-Shell. After having used the shell with the Mark Williams C Compiler for about 6 or 7 months now, I feel it is currently the only viable way to get any real work done on the ST. The system has a few problems but they are minor irretants at best.

Most of the stuff that I have been working on (Both a port of YACC and LEX for the ST among others like cpio and tar) work only with command line arguments whick the MT Shell handles well. If I had to try to develope these without the aid of the MT Shell It would definitely have taken much longer.

I feel that the introduction of a public domain Multi tasking system for the ST would encourage other users to develope more software for the ST. Lets face it the run of the mill software available for the ST is either games, mediocre, or non existent. The best thing I have seen is the Mark Williams C and the MT Shell with the Micro C Tools. Any thing else (with maybe the exception of the developers MODULA II and being a UNIX buff I can't stand anything remotely resembling PASCAL) is nearly imposible to get anything constructive done with.

So my vote goes to a definit yes for putting Beckmeyers MT Shell out on public domain, and Brovo to Mr. Beckmeyer for sugesting it. We need more people actively trying to make the ST a users and developers machine. Maybe someday Atari will even get away from the game machine stigma.

>
Yes, she is gracious. Lovely accent.

>Unfortunately, she had bad news - Laser C wouldn't be shipping until mid
>February or early March. (In December, they were to ship in January). Seems
>that the printer is taking longer than estimated.
>
I have repeatedly had problems with Megamax shipping product. They put me off for about 4 months back when they first brought out their ST compiler, with various printer problems and the like. I finally got a compiler from them on two disks with a scribbled-on Mac version of the manual after much hassle and a large long-distance bill. More recently, I tried for over 6 months to buy the Mac version for a project at work. This time I went through a store, thinking (perhaps naively) that this would give me a bit more leverage. About two months in, it became clear they were not really going to have one "in a couple of weeks", so I began exploring other local stores looking for a copy. To make a long story short, it turned out that THEY WERE NOT SHIPPING PRODUCT! They were out of the old Mac version, and the XL version was not done. I gave up after 6 months of being strung along, and do not even want to discuss what this did to the project. The point of this is, I am firmly convinced that it is their POLICY to promise software RSN, no matter how far it is from completion or what the true problem is. I have many more details if anyone is interested, as the two episodes each went on for far too long. Expect Laser C to ship whenever they get around to it, and not a moment before.

>I guess they use the same printer as OSS and Atari. - Probably Gutenberg.
>
> *sigh*
Indeed. I believe this is called vapor-lock.

>
> < dave stampf
>
>(With all of this desktop publishing around, why can't anyone get anything
>published?!?!?!)

As I say, this is a smokescreen. Call repeatedly over a couple of days, and watch their story change. Go with Mark Williams, they know how to produce, ship, and support products!

I have a hard time taking the "there is no such thing as intellectual property" people seriously, because of one simple observation:

Before the days of personal computers and software for them, I don't _ever_ recall hearing _serious_ discussions about whether intellectual property (as in copyrights for books, records, etc; or patents for objects/processes) _existed_ - though I do recall discussion about how long such things ought to run and what was covered by them.

It is therefore hard for me to believe that this "philosophy" is motivated by anything more than rationalization.

This is not necessarily an opinion, just an observation.

Subject: Re: Lyco Computer

Way back when I had an 800XL and lusting after a 300 baud modem,
I picked Lyco to buy my XM301 from. Terrible choice. I ordered
the product through the mail, and upon calling them a few days later,
I was told that my order had been recieved and sent out.

Wrong. I believed them. A week later, I called again and they said
that my modem was shipped the day before (six days AFTER the original
person said it was sent), and so I waited a week again. Seven days
later, the modem still wasn't here, and I began to call them once a
day. Each time, I got a different story ("it was sent out yesterday",
"our records show that we haven't sent it yet due to a late shipment on
the part of Atari", "it will be taken care of", etc...).

Eventually, to my surprise, it DID get to me, and I vowed never to
even contemplate shopping with them again. A friend of mine had
similar troubles with a modem for his C64 last year (although he had
no trouble when he had bought other goods previously). Either they
hate modem users, or you have a random chance of getting average service.

I personally tend to shop from Computer Mail Order -- they are always
on time, have nice prices, and are reasonable when your package comes
in the mail broken.

As promised, the site administrator/postmaster of CANADA01.BITNET (that BITNET site which is apparently responsible for the bad mail header munging that causes bounced INFO-ATARI16 digests to go back out to the whole world) is Les Dennis <DENNIS@CANADA01.BITNET> (use your favorite BITNET gateway to get there; "psuvax1" for those of you in UUCP land, "cunyvm.cuny.edu" for those of you on the Internet).

Be polite, but insistent; we musn't let them get away with this sort of highly improper network behavior.

Where is Mr. Protocol when I need him?

This is very important to me, so if you have any clue tell me asap!

I intended to order an Atari 1040 ST color system today. I have been slavishly saving my money for months and months now, only to have the price raised on me again and again. This upsets me. But then the clincher:

NOBODY HAS THE ST IN STOCK!

I called CMO, Lyco, Bay Express, All the mail order firms I could get my hands on and a couple of local ones too. And NOT ONE of them had the 1040 in stock and did not expect to for 2-3 weeks.

What the heck? I want to order now, and I don't want to have to put up with another price increase. If anyone knows of anywhere that I can order from mailorder with a total *including shipping* of $1010 or less, REPLY.

Would somone from Atari care to explain whatever happened to their motto?

> the output of one of these programs to an ascii file rather than the printer.

You can redirect the output to printer in your program via the
following:

```
#define PRN 3
#define NULL ((char *) 0L)
...
/*
Put the command parameters in tail[1...]. tail[0] should
equal the number of characters in the command tail, up to 127
(I think - it seems to work).
*/
char tail[128];
...
/*
Force the printer handle to point to the disk file instead.
*/
Fforce(PRN, "disk:/file/name/path.ext");

/*
Now execute the program, the standard handles are inherited.
*/
Pexec(0, "disk:/program/name/path.prg", NULL, tail);
....
```

Hope this helps whoever it was!

> never happens - The authors have put a fair amount of work into this
> thing).

Nah, it just makes the copying more interesting! The SOBs are not the ones who 'crack' programs, they are the ones who copy-protect them in the first place. The U.S. copyright laws GAURANTEE the right of the owner(s) of computer software to backup their programs for archival purposes; copy protection intrudes on that right and should be illegal! The reproducible key method is no better than any other method of copy protection, you can't back up the key, and you can't run the program without the key disk. It's also quite a bit easier to get around than most kinds of copy protection, but that's another topic.

Well, lets try to get away from the hyperbole and into the more mundane realm of facts ("Just the facts, ma'am.") ROM'ed GEM/TOS is 192K. This is by no stretch of the imagination `megabytes.' I might also point out that the cartridge port supports only 128K. Perhaps extensions to the ROM code could go in here, but there's not room for much more.

There's no particular reason why someone (why should it be Atari? they don't do anything else, I don't expect them to do this either...) couldn't make a disk-bootable version of TOS/GEM/GDOS. The hooks are right there in the current ROM versions. It could be updated *frequently*; and it wouldn't compromise the use of the cart port, which I appreciate since my Magic Sac lives in there. It might take up 250K, which I view as cheap in view of the memory sizes which are becoming common with the introduction of the ST-{2,4}'s.

/* fierce flames follow; the weak of heart may press N at this juncture */

Unfortunately, the whole thing has convinced me that Atari has, for all intents and purposes, abandoned GEM. Fine; I am seriously considering abandoning Atari. Especially in view of the "Moses Promised LAN" fiasco (was ever a product given such a stupid name?). I called Atari Canada last week, asking about availability. I was told 3rd or 4th quarter 88. Now, as I remember, this thing was announced 4th quarter 87. What was that all about, perhaps a way of conducting a straw poll? "If enough people call us, we'll consider building the thing; and we won't have to pay for market research." Or maybe they wanted to force someone out of the Atari-LAN market by making customers play wait-and-see? In either case, I am not impressed.

In this context, I might also mention the vapourware ibm-pc gadget that was supposed to hook up to the DMA port and give msdos compatability for a reasonable price; that got lots of airplay and then sank without a trace - the PC-1 is *not* that product, I have seen it and it does not need an ST to operate. (As an aside, the PC-1 appears to "fill a much-needed gap"; it's too small and too unexpandable to be anything more than the VIC20 of the msdos world.)

To clarify my attitudes a bit, let me explain that In The Beginning, I was really taken with the ST's, and recommended them to my friends and to people around the University generally. I knew there were shortcomings and bugs, but my basic faith in the good intentions of vendors led me to think that fixes, as the product became more popular and started to generate cashflow for Atari, would be forthcoming. I defended the things against various stacked benchmarks (the utterly stupid Byte reviews come to minla.(I showed anyone who would look the neat demo's, and promised nifty app's. Subsequent reality has been disappointing.

So far, I have seen one (1) fix, and one (1) enhancement. The fix is FOLDERXXX; the enhancement is HINSTALL. And I (the University, really) am a registered developer. Ghods know what the rest of the world has gotten. I have also seen a lot of flashy but shoddy applications software. Who cares if a database has a wonderful GEM interface, if it crashes every time someone sneezes? Who cares if a spreadsheet is a perfect Lotus-clone, if it goes into hyperspace at random intervals? And in a similar vein, who cares if TOS is a decent msdos clone or not, if it's disk i/o is slower than molasses in January? My totally obsolete H89 (8-bit Heathkit with no disk controller and no dma) created and deleted files faster! Darn right it cached the FAT's, and with only 48K to play with, too.

So I have been left with a certain amount of egg on my face, and a certain unpleasant taste in my mouth, vis-a-vis my earlier enthusiasm and recommendations.

For what it's worth, I now am recommending Amstrads for the typical pc-buyer (you know, the word-bashing and spreadsheet type of user), and Amigas to the serious graphics freaks. I recommend ST's only to the hacker types who write most of their own stuff, and who aren't especially graphics oriented (so far, I am about the only person I know in this latter category), or to people who can't afford Mac's and want to do el-cheapo desktop publishing.

Perhaps the release of Idris will be the turning point, although I have seen Atari snatch defeat from the jaws of victory once too often. What I am really waiting for is Minix. Yes, it has bugs; no, there's not much running on it. But we will have SOURCE, and be out from under the thumb of a certain Business-Is-War type who obviously thinks customers are cattle. Fine; let him do his business without me.

If you are not into Atari ST, or the Icon programming language,
just go to the next message of your favorite mailer.

++++++++++++++++++++++++++

ICON 6.5 (Implementation revision (e)) for the ATARI ST
has been sent to some people.

As the files are quite large, and I do not wish to abuse the local
mailer, I will ask any further request to be redirected to the nearest
person that already have it.

Here is the list where the binaries have been sent:

Vitas P. rochester!ritcv!vxp6840 (uucp)
Denise ? rochester!ritcv!dsh3059 (uucp)
Mark Storin ihnp4!uwmcsd1!lakesys!mark (uucp)
Marty Wiedmeyer ihnp4!uwmcsd1!lakesys!martin (uucp)
Rich ? ihnp4!uwmcsd1!lakesys!rich (uucp)
Plinio Barbeito acm@valhalla.cs.ucla.edu (edu)
Bertrand Decouty decouty@frcicg71 (earn)
Klaus Hahn hahn_k@dmrhrz11 (earn)
Greg Onufer ucbvax!ucdavis!uop.edu!root (uucp)
Andres F. Moreno moreno@umn-cs.cs.umn.edu (edu)
Bob Bright bright@dalac (bitnet)
Matthias Moritz u608017@hnykun11 (earn)
Ruud van der Plaats vdplaats@hnykun53 (earn)
Gordon Joly gcj%@uk.ac.qmc.maths (uk)
Rick Fonorow ihnp4!ihlpe!orf (uucp)
Wilfried Bloemberg fonetiek@hnykun52 (earn)
Jerry Nowlin ihnp4!ihuxy!nowlin (uucp)

The sources will not be distributed by me, They have been sent to
the Icon project at U. of Arizona, and to the 2 original implementors.

Some of you asked for some documentation on ICON or on this peculiar
version: I can send upon request the article on Icon version 6 from
U. of Arizona, and the various files that come with the former
implementation.

The reference book for the language beeing the book:
Griswold, Ralph E. and Madge T. Griswold. The Icon Programming
Language, Prentice-Hall, Inc., Englewood Cliffs, New Jersey.
1983.

Send all inquiries to icon-project@arizona.edu

++++++++++++++++++++++++

Notes on this (e) implementation:

-It is done using MCC Lattice 3.04 C compiler, with sources coming
from U. of Az (Rick Fonorow & Jerry Nowlin, made it for the 3.03 C).
I added the support for various missing stuff, the arithmetic overflow
and Co-expression assembly code was furnished to me by Ralph Griswold.
Ralph did answer to all questions that allowed me to bring this code up.

-All binaries are called .TTP in order to be called from the desktop,
without using a shell if you dont like it, or if you are short in memory.
I used/developped the thing on a 1040ST Monochrome, with a 400K
ram-disk. I think iconx.ttp will work on 520ST, with TOS in ROM.
Iconx.ttp takes 200K for the heap, and 10K for the stack, plus data
and text segment.

-If you want to use icont: it will attempt to find itran/ilink/iconx
by looking at the ICON environment variable, that should be set to
the disk/directory where these can be found, then it will try for the
PATH variable, then for the root directory of all currently mounted
disk drives, in alphabetical order.
If you are invoking icont.ttp from the desktop, you can tell where are
the other binaries by the "-p disk:\dir" option.
All options to icont can be in upper or lower case.

-If you want to use a very large Icon program, you may have to
increase some memory area, in this case, you will have to tell the
startup code of Iconx, with the % option, before all other arguments
on the command line. {iconx> is currently equivalent to <iconx %200000>,
you may have to try %300000 or more. The number after % is the total
heap size, in byte.)

-If you want to use the system() call, find a shell that can do what
you want... I have'nt yet...
Iconx will look into the SHELL environment variable, it should be set
to the complete filename of the shell you want to invoke.
I have tried PCOMMAND, ASH, MSH, COMMAND.TOS, and the lowly last one
gave me best results... (most shells are not able to understand
arguments passed to them, if this is an internal command, they
always try to "fork" it...)
(In fact it does not need to be a shell, just any program can be
"forked", args passed, and the exit code will be returned back.)
(I am still looking for the sources of a good shell that I can hack
and make useful on the ST, whatever be your keyboard religion.)

I would appreciate any hints of bugs, to be reported, altough
it may take time to fix... may be version 7...

Regards,

Jean-Pierre H. Dumas

There _could_ be a standard "doohickey" as the originator of this discussion wants...

A company named Software Security has an add in Dr. Dobbs journal. They have a devie which plugs into the parrallel port of _any_ computer that has one (good for the ST's and such since a parallel port is standard equipment!). It does not interfere with normal parallel port use since it is daisy-chained (and even allows more then one such 'key' device in that chain!). Each 'key' has a number readable by software in it.

Drawbacks: this company has it patented..they will make all the money.
But since it is patented...pirates will have a helluva time making duplicates.
Correct me if I am wrong, but patent laws are far more enforcable than Copyright laws!!!

For info: Software Security, 870 High Ridge Rd, Stamford Connecticut 06905
203-329-8870

DISCLAIMER: I only saw their ad. I will not be making money off of this nor do I want to. In fact, although I think this is a great idea, I do not own the patents....so I could care less.

Greg Onufer

****
****

I recently bought my 520STfm from them at $479 for the system (which I
believe has since gone up) and am satisfied (that was a mono sys).

The SM124 monitor was not working when I received it so I called them up
and the girl on the other end was reaaly quite nice, said to send it
back, and they would send me a new one. They shipped me the new one the
same day they got the old one and it works (using it this minute).

I will do things with them in the future but I alse try to frequent
local computer stores to help them out with business and to establish
good relationships with them. As a student with limited resources,
I am grateful that mail order exists.

Hope that helped.

It's hard to do useful work with books (write a list of numbers in a
book and put @sum(a1..a7) at the bottom of them :-), records, etc., and
it's similarly hard to copy them. It's easy to do useful work with
computer software, and it's similarly easy to copy them.

> (desktop, or other...) it is in the local shell variable 'calledfrom'.
>An other shell is able to tell the list of all parents programs...
>The base page does not contain any backward pointer, so what is it ?

The answer to this is that msh looks at the environment strings to determine
whether a the MWC environment is already there and if it is, it determines
how it was run, otherwise, it figures that it must be the desktop. It
can check for \auto because the GEM stuff is not set up yet.

There is, in fact, a 'backward' pointer to the parent process basepage
in the program basepage. This is documented in the include file
'basepage.h' supplied with Mark Williams C, though not in the manual.
It is at offset 0x24 from the beginning of the basepage. There is a
LOT of information in the basepage that was not initially documented
by Atari.

From: jsm@laird.UUCP
Message-ID: <12.UUL1.1#125@laird.UUCP>
Source record: 254708

There is already a PD Multi-tasking program for the ST. It is called MX2. There was a previous release called AMulti. In addition all the sources are availabe from the author for only $20. It works well with Gulam. If this message gets out (I have tried to post before and failed) and if other people are interrested I will post the documentation files for it.

The fact that the sources are available at a minimal cost is a big reason why I prefer this one. One word of warning though; it is NOT in C. The program was written in Modula 2. C programs run just fine under it though :-).

It is also available for download from Gateway BBS, (801) 562-1587, 300/1200/2400 baud.

(I really hope this message gets out. It would really be nice to be able to post messages. If you read this, how about dropping me a line and telling me that it did get out.)

>publishing program.
>
>-or-
>I buy a mono-ST for .9K and a AST Turbo Laser for $3K -> for a total of
>$3.9K.
>I have the same software.

I'm using the Atari laser for about two months now and I find it
wonderfull. Just compare its 'black' with most other lasers.

But let me ask you same questions:

Do you have a 'GDOS'-printerdriver for the AST-turbo-laser?
Can you make a screendump to the AST-laser?
The programs that you have or you'll have in the future, are they
supporting the AST-laser?
Do you have a 'epson'-emulator for the AST-laser? (a German-company is
selling one for the Atari-laser)

I think, if you are sure you don't sell your ST in the near future, you
will be better of with the Atari laser.
I'm very sure some smart company will make a RS232- or centronics-
interface for the Atari-laser.
I'm sure some smart guy will write a fonteditor for the Atari-laser.

I agree, it's sometimes a wast of time waiting to get the ST back when
the laser is printing.

.... Much as I hate the Intel architecture, my brother has an AT clone
running MicroPort System 5 and it works pretty well. But a 68030
machine can only improve the situation. I like others I have heard on
this sig have been sorely disappointed with Atari's ability to support
the St series. To know that a machine I have heard about being in the
works for over 2 years now, will finally come out is at least one step
forward. However, I don't know what this says for Atari. Any other
company that takes that long to bring out a promised machine would have
been out of business long before now. Well enough of the bitch'n for I
am still eagerly awaiting the anouncement of the TT (or whatever they
call it).

What DOES need multi-tasking in the above example (though not perfectly spelled out) is that if I'm editing a file, the formatting requires attention from the system as well. Not just "suspend" the word processor and do the format. So, whether it is implemented using TSR's or not, you do have concurrently running processes. This is not the same as having two TSR's that you hot-key between. There is a difference. The topic is multi-tasking, is it useful for the typical user?, and the answer is yes, no matter how it is implemented.

What us Amiga users say beyond that, is that multi-tasking meaning having a task table and such, is a better implementation than using TSR's. Using TSR's means adding more code to each program that handles hot-keys. To trap the interrupt, etc. The Mac's implementation of Juggler looks extremely sophisticated for what should be a simple issue: give my process some of the CPU time.

I'll agree, it may be somewhat misleading that the Amiga advertising implies that only the Amiga has multi-tasking. Butj, it supports it better than MS-DOS, TOS, or Juggler. But, to explain the difference in a 30-second clip, well ... :-)

YES, YES, this is running on ....

1513. Re: Mediach() function question

Newsgroup: comp.sys.atari.st
Date: 1988-02-02 19:12:58 UTC
From: fischer-michael@YALE.ARPA
Message-ID: <8802021912.AA05940@ELI.CS.YALE.EDU>
Source record: 254713

Karl Rowley asks:
> I have a question about the GEMDOS Mediach() function. My MWC manual says
> this function can return a 0, 1, or 2, meaning "no", "maybe", or "yes."
> What situation would cause Mediach() to return "maybe"?

"maybe" is returned after a short time (on the order of 1-2 seconds)
has elapsed with no disk activity if the write protect latch has
seen light, which occurs whenever the disk is removed from the drive
but also whenever a disk is write protected. Rwabs responds to
"maybe" by rereading the boot sector and seeing if the 24 bit serial
number written there agrees with the remembered value. If so, it
assumes the disk has NOT changed, so it sets the media change value
back to 0 and carries out the request; if not it sets it to 2 and
returns a "media changed" error. (This also occurs if it was 2
to start with.) Getbpb is what normally sets it back to 0.

The idea is that a disk cannot be changed without the system noticing
and checking the serial number. If the disk is write protected,
the boot sector will be read more often than necessary but otherwise
no harm is done. Too bad if you are unlucky enough to have two
disks with the same id and you insert one right after the other.
Gemdos will not notice that the disks have been changed and will
happily clobber the second disk if you attempt to write on it since
it will use cached FAT information from the first. Note that this
situation (of duplicate disk ids) will occur with certain copy
programs that copy the entire disk, including the boot sector. Avoid
using them for making backups of ordinary data disks.

1514. Printing the screen on non Epson/Atari printers

Newsgroup: comp.sys.atari.st
Date: 1988-02-02 20:25:28 UTC
From: gert@prls.UUCP
Message-ID: <8835@prls.UUCP>
Source record: 254714

Yesterday I decided to hack up a driver that will allow me to
do a graphics screendump using the GEM menu command 'print screen'
or the <ALT> HELP keycommand on my C-Itoh 8600M printer.

I realise that this effort is probably double work, I'm sure
somebody must allready have done this for other non Epson
printers.

Questions :

1 - If you have a binary driver for C-Itoh 8600 or source to
another printer driver, please mail it to me.

2 - Does anybody have the _prtblk documentation. It is missing
in my (very early) development kit. It looks like that
code is general enough to handle screendumps to any printer,
if I only knew its parameter block meaning.

3 - Does anybody know a (assembly level) call to the equivalent
of bconout(0) that works from inside my screendump handler
(that is called from the BIOS through the $502 vector).
Claims that the BIOS is reentrant seem to be contradicted :
using the normal trap interface to bconout hangs the system.

Offer :

if you are interested in such a driver, you are welcome to my
source and code once I solve the problems. Mail me.

Gert Slavenburg

> this function can return a 0, 1, or 2, meaning "no", "maybe", or "yes."
> What situation would cause Mediach() to return "maybe"?

"Maybe" means that the disk was ejected, but the same disk might have
been put back in the drive. When the drive is in this state, the next
access will cause the BIOS to check the serial number against the last
disk that was there: if they match, then the media hasn't really
changed, and the operation succeeds. If they don't match, that
operation returns the "media changed" error.

>
> And later we fixed all those problems and then forgot about it. I don't think
> there's anyone here still working on GEMDOS.

I take issue with the second paragraph: it took DRI (in the person of
that wonder-programmer mentioned above) a *long* time to come up with
anything new, and when they did, it still had bugs. I noticed one in
the first day of testing it. (Dirty buffers would get flushed to disk
at odd times, later than you expect.) We (Atari) decided not to trade a
set of known bugs for a set of unknown ones, so we didn't adopt this
"DOS 1.1" from DRI.

While there may be nobody at DRI working on GEMDOS, there sure is somebody
at Atari working on it. Stay tuned for more details.

> Is there a better substitute for MUSHROOM, or
> documentation on where to find the crash data and how to interpret it?

If you mean the MUSHROOM.PRG from Silas Warner (a PLATO programmer from way back, and author of Castle Lichtenstein (?) on the Apple][), it does work as far as it goes, but then it causes bombs and overwrites all that stack information.

There is no TOS call to get control in bomb-like situations. Since you ask for one, it is possible that you don't have enough understanding of 68000 exceptions to port the debugger. I wrote an ultra-cool debugger for the ST, and it handles all the bomb-type errors. You have to take over the exceptions (bus error, address error, illegal instruction, etc.) yourself.

The Hitchhiker's Guide to the BIOS has the definitive description of the bomb-save area. It contains the values of all the registers, including PC, USP, and SSP, and the top few words of the supervisor stack at the time of the bomb. The format can be found in the Guide, and possibly in such places as Abacus books (but I *never* trust an Abacus book to get it right.)

I do not consider it a flame against me (The Keeper of GEMDOS and Loremaster) when you slam GEMDOS. The programmer mentioned elsewhere in this newsgroup (since Bruce Holloway didn't mention his name, I won't either) is the culprit, and I have been fixing his code for the last four months. I have put out the worst fires, but I don't ever see this version of GEMDOS matching MS-DOS 3.x... It would take a complete rewrite.

Even so, I have killed the 40-folder bug, fixed Malloc, and removed the molasses from the FAT handling code, plus lots of other, more minor fixes. Sorry about teasing you with this stuff, but I don't know how or when it will be released. One good possibility is as a RAM-loaded upgrade (only 32K, not 200K like RAM TOS was).

There have been arguments about copyrights on music ever since the advent
of cassette tape, and there are also arguments (though fewer, owing to the
increased difficulty) over copying from books without the author's
permission. The only thing to really compare software piracy to is
record piracy.

But with me, it's all pretty moot because honestly, I really don't
give a damn about morals.

1522. Mark Williams C

Newsgroup: comp.sys.atari.st
Date: 1988-02-02 23:08:52 UTC
From: wolf@csclea.ncsu.edu
Message-ID: <1442@ncsuvx.ncsu.edu>
Source record: 254722

It seems that Mark Williams C is one of the more popular C compilers for the ST. Well, I've had my copy (an early v1.2) for more than a year now and am ALMOST happy with it: I can't stand the speed (or lack thereof) of the compile/link phase. Even after optimization (letting the compiler put temp files in ram-disk), my hard-disk based system still took over 5 minutes to 'make' a 3-module (total < 1200 lines) program. That's an average compile/link time of 220 lines/minute! MW-Quick C and Turbo-C for the PC's supposedly compile/link 10,000+ lines/minute. Could that be?

Am I just TOO impatient? After all, it gives me time to fix a cup of tea while I wait for compiles/links :-)

I didn't bother upgrading to v2.0, since I didn't detect any significant speed improvements (and the cost was $50.00 -- for an UPGRADE!) when I tried it out on a friends machine.

Could some kind soul post (or send to me) some compile benchmarks for the newest MW-C ? (Is it v2.17?) If possible, I'd hope to see a benchmark for APSKEL.PRG -- but even a 'hello world' result would be appreciated. Perhaps this info will help me decide whether I want to upgrade to the new MW or just wait for Laser-C by Megamax.

Thanks in advance for any info.

Tom Wolf

1523. ST ROM BIOS BUG: Reset bailout vector

Newsgroup: comp.sys.atari.st
Date: 1988-02-03 00:03:45 UTC
From: apratt@atari.UUCP
Message-ID: <970@atari.UUCP>
Source record: 254723

I have just discovered a bug in the ST ROM BIOS (both "old ROMs" and Mega ROMs): the system variable resvector ($42a long) is not used the way it's defined in the Guide (or anywhere else).

This vector is supposed to be called early in system initialization, after the memory controller has been programmed but before any memory has been touched (in a warm boot). Since there is no stack pointer yet (you're still at IPL 7), the return address is passed in a6.

The bug is that a6 points to the wrong thing. It's a stupid programmer error: the line should have been "lea.l reset3(pc),a6" but "reset2" was used instead.

The workaround is to check to see if (a6).w == $9bcd. If it is, then you should return to the ROMs with "jmp $24(a6)" and if it isn't, then return with "jmp (a6)" as advertised.

((a6).w will not equal $9bcd in future ROMs where the bug has been fixed.)

So your "return to ROMs" code, after doing whatever you want to do at reset time, should look like this:

```
cmp.w #$9bcd,(a6) ; check the instruction at (a6)
beq.s buggy_rom ; if eq, it's the old, buggy version
jmp (a6) ; return to ROMs (new version)

buggy_rom:
jmp $24(a6) ; return to ROMs (buggy version)
```

****

Brought to you by the Atari Programmer's Service Bureau (Allan Pratt, Chief Loremaster).

Obviously Mr. Santangeli hasn't used a TRS-80 in some time. LS-DOS
6.3 compares to the early versions of TRSDOS much as (name your favorite
well-thought-out, essentially bugless OS) compares to early versions of
CP/M.

The stuff referred to in the original articles (which info-atari
sends out to bitnet) is in the form of DIGESTS, so there isn't any one author.
The sender is therefore "info-atari", and replies to that address are
sent out to the newsgroup. That's how it all works, and except for
occasional glitches, it's pretty reasonable overall..

I tend to disagree with this statement. Mainly because the 520 now
sports an internal single sided drive. This makes it much more difficult to
upgrade to double sided drives. The old 520's had external drives. Much
easier to upgrade.

It also makes more sense to go with a full meg right away. Soon
applications will be expecting a meg (what with the Mega's being out). Why go
thru the extra hassle of doing a memory upgrade (which I believe he would want
to do right away if he got a 520).

========== NEWS !!!!!!!!!! ==========

I called Mark Williams today for a little problem and was told that the new version of MWC was to be released now. Meaning: Feb. 2, 1988.

BEST news: includes CSD, source-level debugger!! (Can Laser C do dat?)

Sales at MW Co. was supposed to call me back after their lunch time, but never did (or I was out). I am ordering tomorrow.

This should be good news to you MWC lovers out there!!

I am looking for the same thing. Maybe there's enough interest to justify
a repost in this newsgroup. A version that compiles with Mark Williams C
is preferred.

Thanks,
Kees Verstoep.

1534. Avoiding Ctrl-C

Newsgroup: comp.sys.atari.st
Date: 1988-02-03 12:13:51 UTC
From: t68@nikhefh.hep.nl
Message-ID: <427@nikhefh.hep.nl>
Source record: 254734

The use of interrupts via Ctrl-C is purely limited to calls to Gemdos.
When the normal I/O functions of Gemdos are called and there is a need
to put a character on the screen there is first a check whether the
BIOS (via Bconstat) has a new character and if so whether this is one
of the special characters (Ctrl-S, Ctrl-Q, Ctrl-C and a few more).
If so the appropriate action is taken. This makes it necessary for
Gemdos to have its own input buffers. During the programming there
came a small bug in those and if one has a program that uses input
characters, but slower than the user types them in it is possible to
crash (hard to do intentionally).
If there is a need to circumvent the Ctrl-C there are two possibilities:
1: use Crawio for all screen I/O. This is one of the few Gemdos functions
that doesn't test for Ctrl-C etc.
2: Get the characters via Bconin and write them via Bconout. This last
method is the faster, but in a shell it is now impossible to redirect
the screen I/O. Using Bconout with device number 5 allows the user
to also put the non ASCII characters on the screen.

Concerning the above bug and the recent remark from DRI:
I think it is quite impressive that one person put Gemdos together in one
month. It leaves however more questions than were answered:
Why is it then so difficult to have somebody spend another month making it
into a great file system with speed and even fewer bugs?
It would result in something that DRI could be proud of rather than that
many people complain about the piece of work that they sold.
What are the great programs that this kind of people make during all
those other months?

1535. Demo of the english version of TEMPUS

Newsgroup: comp.sys.atari.st
Date: 1988-02-03 13:24:00 UTC
From: FKERONNE@HLERUL52.BITNET
Message-ID: <8802031847.AA21309@ucbvax.Berkeley.EDU>
Source record: 254735

Hi netfolks,

Recently I found the german demo of the ascii text editor named "TEMPUS",
in the download there was a remark that the demo would bomb, so it would
be a limitted demonstration.

But I was amazed by the speed of this editor, so I decided to get my own
english version of TEMPUS. The version I got was TEMPUS1.10.

On the disk there was a *working* demo of TEMPUS, which of course is not
able to do savings and printings of edited texts.

The uuencoded file is about 64K, which is to large to post it to this list,
the uuencoded/arced demo has been posted to the prog-16 filelist on
listserv@canada01 (earn/bitnet).

I also heard from SoftPaquet (Zoetermeer, Holland) that in september 1988
a textprocessor/editor based on TEMPUS will be released, so get it when it
is releassed, get it then, but first buy the ascii text editor!!!!!

Disclaimer: I'm just a customer that's happy with TEMPUS!!!!

Greetings,
Victor Ronnen
(EARN/BITNET adress: FKERONNE@HLERUL52)

1536. Re: Laser Printers and the ST

Newsgroup: comp.sys.atari.st
Date: 1988-02-03 14:13:50 UTC
From: drs@bnl.ARPA
Message-ID: <324@bnl.ARPA>
Source record: 254736

In article <8802021704.AA24124@ucbvax.Berkeley.EDU> GASPARD@HROEUR5.BITNET writes:

>>I have the same software.
>
>
>I'm using the Atari laser for about two months now and I find it
>wonderfull. Just compare its 'black' with most other lasers.
>

I did, and I wasn't terribly impressed - but then it could have been a lot
of other factors including that the salesman didn't show it off to its best
advantage.

>But let me ask you same questions:
>
>Do you have a 'GDOS'-printerdriver for the AST-turbo-laser?

Who cares - I haven't seen GDOS out of atari yet and I won't spend $2000 to
get it.

>Can you make a screendump to the AST-laser?

I've taken a total of 2 screen dumps - mostly to see if the printer was hooked
up. That isn't what I want a laser printer for.

>The programs that you have or you'll have in the future, are they
>supporting the AST-laser?

Since the AST runs postscript, I would imagine that the number of programs that
support it far outnumber those that support the Atari Laser. In addition,
there are a lot of folks out there who know postscript. It simply blows away
all other page description languages (in my opinion!)

>Do you have a 'epson'-emulator for the AST-laser? (a German-company is
>selling one for the Atari-laser)

Maybe I'm missing the point, but why buy a printer that costs an order of magnitude more than the epson so I can emulate the epson? The epson is a simple printer and anyone who can write a program around a finite state machine can write an emulator for it.

>I think, if you are sure you don't sell your ST in the near future, you
>will be better of with the Atari laser.
>I'm very sure some smart company will make a RS232- or centronics-
>interface for the Atari-laser.

Well don't hold your breath, but I would not care to add $200 to an already overpriced printer to make it useful to other machines - besides, since the Atari laser has NO memory, the interface would have to run at a speed matching the construction of the image - I don't know that the serial line can do it, and even the Centronics may be too slow. (A full graphics page takes about 2 minutes to download at 9600 baud - that's why you want the printer to have some smarts and build the image itself.)

>I'm sure some smart guy will write a fonteditor for the Atari-laser.
>
>I agree, it's sometimes a wast of time waiting to get the ST back when
>the laser is printing.
>

And paying double for the privilege is a real insult.

>
>Bert Rozenberg
>Dutch ST-foundation.

Had this printer had a street price of < $1K, it would be a deal, but at double that ... Sorry.

```
<dumas@sumex-aim.stanford.edu> writes...
> Question #1 : How MWC's msh is discovering who called it ?
> (desktop, or other...) it is in the local shell variable 'calledfrom'.
> An other shell is able to tell the list of all parents programs...
> The base page does not contain any backward pointer, so what is it ?

I'm not sure that MSH does* detect being called from the desktop. What
difference would it make (or does it in MSH). The basepage, however,
DOES* contain a "backward pointer" to the parent processes basepage.
Here is a struct to clarify...

typedef struct
{
char *p_lowtpa; /* pointer to self (bottom of TPA) */
char *p_hitpa; /* pointer to top of TPA + 1 */
char *p_tbase; /* base of text segment */
long p_tlen; /* length of text segment */
char *p_dbase; /* base of data segment */
long p_dlen; /* length of data segment */
char *p_bbase; /* base of BSS segment */
long p_blen; /* length of BSS segment */
char *p_dta; /* pointer to current DTA */
char *p_parent; /* pointer to parent's basepage */
char *p_reserved; /* reserved for future use */
char *p_env; /* pointer to environment string */
long p_undefined[20]; /* scratch area... don't touch */
char p_cmdlin[128]; /* command line image */
}
BASEPAGE;

> Question #2 : I read again the dev kit doc on shell_p, the posting
> by A.Pratt about it, and I still wonder : what is it ?
> I would infer it is a pointer to a string telling the file name of a shell...
> I am right ?
> What would be the use otherwise ?

The shell_p variable, if it is valid, should point to a routine which
will take a string argument and process it like the Un*x system() call.
Here is an example implementation of system() which tries to use the
shell_p variable, if possible.

/*--------------------------------------------------------------------*/
#include <osbind.h>
#include <stdio.h>
#include <string.h>
#include <basepage.h>
```

```
static parse_args(cmdln, argv)
char *cmdln;
register char *argv[];
{
register char *p;
static char delim[] = " \t\r\n";

if(p = strtok(cmdln, delim))
{
do
{
*argv++ = p;
} while(p = strtok(NULL, delim));
}
}

int system(command)
register char *command;
/*
* Attempts to pass <command> to the shell program pointed to by
* the system variable "_shell_p". If a valid shell can't be found
* there, the "SHELL" environment variable is searched for. If it
* exists and is not empty, it will be the name of the shell program
* to execute the given command. If "SHELL" is not valid, the
* "PATH" variable is used as a list of directories to search for
* the program name which is the first token of the command. The
* extensions tried (if none is specified) are ".TTP", ".TOS",
* ".PRG" and ".APP".
*/
{
register char *p;
register int (*shell)();
char rv[2];
char cmdln[1024];
char *args[64];
char *getenv();

if(!command)
return(ERROR);

/* get _shell_p value */
p = Super(0L);
shell = *((long *) 0x4F6L);
Super(p);

/* validate _shell_p */
if((shell) && /* Shell available. */
(((long) shell) < ((long) _base)) && /* Reasonable shell pointer. */
(strncmp(shell, "PATH", 4))) /* Not corrupted */
{
/* execute the command */
return((*shell)(command));
}
```

```
/* copy the command line for parsing */
strcpy(cmdln, command);

/* SHELL= variable? */
if((p = getenv("SHELL")) && (*p))
{
args[0] = p;
parse_args(cmdln, args+1);
forkvpe(p, args, NULL);
wait(&rv);
return((rv[1] == 0) ? rv[0] : rv[1]);
}

/* attempt to find first token as a program on the path */
parse_args(cmdln, args);
if(p = pfindfile(args[0], ".ttp\0.tos\0.prg\0.app"))
{
forkvpe(p, args, NULL);
wait(&rv);
return((rv[1] == 0) ? rv[0] : rv[1]);
}
return(ERROR);
}
/*------------------------------------------------------------------------*/
```

I hope this answers your question. It's so easy for a shell to install itself on the shell_p vector and it's so convenient if other program which support shell escapes use a system() call like the one above. In case there is any question about installing and removing the shell_p vector, the following routines will handle it nicely.

```
/*------------------------------------------------------------------------*/
long (*sh_save)(); /* previous value of _shell_p variable */

sh_install(new_shell)
int (*new_shell)();
/*
* install _shell_p vector
*/
{
register long *ssp;
register (**shell_p)() = 0x4F6L;

ssp = Super(0L);
sh_save = *shell_p;
*shell_p = new_shell;
Super(ssp);
}

sh_restore()
/*
* restore old _shell_p vector
*/
```

```
{
register long *ssp;
register (**shell_p)() = 0x4F6L;

ssp = Super(0L);
*shell_p = sh_save;
Super(ssp);
}
/*--------------------------------------------------------------------*/
```

PS. For those waiting for dLibs v1.1 and/or MicroEMACS 2.19, I have sent out disks for all the requests I had outstanding, you should either already have them, or should receive them soon. Sorry for the delays. I hope you're happy with the results. I'd like to hear from some of you after you've used dLibs a bit. I'd be happy to receive bug reports, suggested enhancements or just experiences so that I know they're being put to good use.

1539. Laser printing from the Atari ST

Newsgroup: comp.sys.atari.st
Date: 1988-02-03 15:37:19 UTC
From: dougie@its63b.ed.ac.uk
Message-ID: <949@its63b.ed.ac.uk>
Source record: 254739

We are investigating the possibility of using our Ataris ST's in conjunction with our Laser printer. The printer is made by Electronic Printing Systems Ltd - Model 4045 CP. The idea would be to produce output from packages such as Easydraw & Dega Elite onto the laser.

Can anyone advise on the feasibility of this, what is involved in interfacing and costs etc ...

Many Thanks,

1540. Re: <Control> C and autostarting GEM programs

Newsgroup: comp.sys.atari.st
Date: 1988-02-03 16:07:34 UTC
From: dclemans@mntgfx.mentor.com
Message-ID: <1988Feb3.080736.14303@mntgfx.mentor.com>
Source record: 254740

Re: Control C

GEMDOS doesn't directly terminate a process when it sees a Control-C character in a "cooked" input function; instead it calls a special pseudo-interrupt vector called the critical exception handler. The default code for that handler is what terminates the process. If you install a replacement for it you can do whatever you want. If I remember correctly this is described in the Atari GEMDOS Users Guide manual.

Re: autostarting GEM programs

My understanding is that what the autostart programs do is to set up a small TSR routine attached to the vertical blank interrupt vector. On each interrupt the code looks around and tries to guess whether or not GEM is initialized yet. If it looks initialized it disengages from the vertical blank interrupt and starts the requested GEM program. Whether or not a specific version of this technique works with all versions of the ROM's depends on specifically how the code checks for GEM being initialized.

> for all partitions (entire hard disk)? What is it?

It is 40 folder ACCESSES across the entire hard disk and floppies.
The limit is imposed by the available directory buffering space on
the ST (a fixed value). With floppies when you change the media
it will free the buffers for directories on the removed media. But
the hard disk never does this so it never unbuffers their directories.

> Another told me it no more than 40 folders in the root directory.

Their is a limit of 256 directory entries on your root os something like
that. But that is a different problem.

From: ted@banyan.UUCP
Message-ID: <237@banyan.UUCP>
Source record: 254744

If anyone knows,

I attempted calling Atari customer support twice today, and cut off on
both occassions without an answer to the following questions:

Is there an update to DBMan v.2.02, and is there an "assist" style
GEM interface available? (Neil??)

On another vain, does anyone have an idea of when Atari will be shipping a
"slotted" PC clone? I know several people (including myself) that would
be interested. I saw the first PC clone Atari announced at an Atari-Fest
several months ago, but have not heard a peep about it since.

Lastly, to the netter who was inquiring about the latest version of
MWC. MW just announce release of version 3.00 in an add in this months Antic.
The add boasts improved optimization (~20% better), a Resource Construction
tool, and for a limited time csd (C source level debugger) at a special low
price. I ordered the 3.0 upgrade with csd for $39.95 which seems reasonable.
MW said that v. 3.0 will not be shipped until around Mar. 1-14th.
I'm currently using v. 2.1.7 of which I have no real complaints. Occassionally
after several hours of use the compiler seems to stop compiling, however I am
using a "real" old 520-ST upgraded to a meg with the Terrific upgrade board and the old MMU
chip, so I suspect the machine. ("Real old" == early 1985
TOS in ROM).

T. Bailey
Banyan Systems, Inc.

I have a related question, having just gotten (re)started on an ST:

Is there or is there not a fix for the 40 folder limit?

I'm confused because I've seen postings that claim new limits of
100, 200, etc. folders, but recently I see that the world is
waiting for Atari's fix of this problem.

Could someone clarify for Robert, me, and other neophyte/non-developer
ST users?

1549. ST -> Mega bus

Newsgroup: comp.sys.atari.st
Date: 1988-02-03 20:27:00 UTC
From: FXDDR@ALASKA.BITNET
Message-ID: <8802040129.AA29125@ucbvax.Berkeley.EDU>
Source record: 254749

The main improvement in the Megas over the STs seems to be the "system expansion bus" which according to the magazines is a 64-pin connector that brings out all of the 68000 lines. So...

Why not take a short piece of ribbon cable, solder one end to the appropriate places on the mother board, and put a backplane with a couple of 64-pin connectors on the other end? That one modification would eliminate the need for any further tinkering 'under the hood', other than replacing ROMs, and as far as I can tell would allow all the Mega toys -- abaqs, laser printers, and more interesting things -- to be plugged into the STs.

And as long as all of the cpu lines were on the backplane board, might as well build a couple of sockets onto the board, one for the blitter and one for a 68881. Might also want a Mega-compatible battery-operated clock out there. Probably would need connections for an external power supply too, since the ST supplies don't have any margin for growth.

Perhaps a Mega hardware hacker can tell me why doing this wouldn't give me the functional equivalent of a Mega. It sounds to me like a cheap one-evening wire-wrap project. Could some kind Mega owner post the connector pinout as a conversation piece?

Thanks,
Don Rice

>handful of people post about what a waste of time and/or net resources it is.
True, only a handful flame, many others merely unsubscribe or stop reading netnews altogether! Others, like me, sit back and wish it would stop, but don't want to add to the waste of space and time by complaining. However, I find it hard to believe that anyone is actually in favor of the incredible, dull repetition of arguments, personal attacks and idiotic assertions common to both sides of these wars!

>First of all, concern about the wasting of net bandwidth are overblown.
True, it's not actual net bandwidth that concerns most of us -- in comparison to some of the bizarre things wandering the net, this stuff isn't so big. It's the consumption of NET READER BANDWIDTH that does it. I am getting over 350 messages a day from four or five groups alone, and have no time to read 50 articles on why software piracy is bad/good, why it is bad to have multitasking or crossposted light bulb jokes and the ensuing complaints! Going away for a weekend or two is a downright scary concept -- I'll never have time to catch up and sift the few good messages out of the heaps of crud!!! I generally don't like moderated groups as they lose the quality of a discussion, but they are starting to look better and better as the percentage of net.bull goes up.

>I mean, hit 'N' if you don't want to read it. ("vn" users have
>an even easier time of it.)
Fine, but when you have to hit N more often than not, something is wrong!

>It breaks up the monotony of all of the useful and informative Amiga messages
>from the likes of Chuck, Fred, Bryce, Leo, George, Carolyn, Andy, Peter et al
Can't believe this -- the monotony of useful and informative messages!?!?!?!?!!
Aieee! Give me more monotony, give me more boredom! Useful messages? Perish the thought!

1552. HELP needed with 5.25" drive hook-up

Newsgroup: comp.sys.atari.st
Date: 1988-02-03 22:45:00 UTC
From: SYSTEM@UVPHYS.BITNET
Message-ID: <8802040058.AA28448@ucbvax.Berkeley.EDU>
Source record: 254602

After reading several digest articles on how to hook up an IBM stule
5.25" drive to the ST, I decided to try it myself.
I used a spare slimline Panasonic 5.25" drive which I tried connecting to
the ST with no success. Here is what I did in case someone could help.

1. bought an atari external floppy DIN cable and cut one of the DIN's off.
2. soldered the bare wires to a 34 pin plug that connects to the edge
connector of the Panasonic drive; here are the pin connections

ST external floppy Panasonic (IBM style)
connector edge connector
1 30
2 32
3 3
4 8
5 12
6 no connection
7 3
8 16
9 18
10 20
11 22
12 24
13 26
14 28

3. had our shop built a power supply and box for the drive

I also removed the 150 ohm resistor (near edge connector of the Panasonic).
The DS jumpers go from 1 to 4 and the jumper is put in position #2.
All other jumpers were left where they were when this drive was on an IBM XT.
I have no special software to take care of the seek rate, and I tried using
the above set up with PC ditto.
Both the ST and PC ditto cannot see the 5.25" drive, although I have installed
both drive A and B.
I get a message, when I select B, to put disk B into drive A.

Any ideas why this set up does not work?

Thank you in advance

I agree with you and I think that there should be discussions regarding pros and cons of different PC hardware and OS -- Amiga, Atari ST, PC/AT/386, PS/2, MAC II, etc.

However, this type of discussions should not be limited to dl's devoted to one brand of PC's, whether it's Amiga or Atari (or IBMPC, or Mac, ...). There should be a separate list for this purpose. Perhaps something like "PCComparison" will be an appropriate name for it.

Actually, I used a model III until recently (2 years). I agree that some
3rd party dos's for the TRS80 put many current OS's to shame. But I said TRSDOS.
I don't consider Radio Shack's switching to LDOS (or whatever) to mean
that it is the same OS. it isn't (I know, switch the posting to comp.sys.trs80..)
No flames please, I was just clarifying. Consider the subject closed.

I guess no one heard me so I'll say it again. I experimented
with GEMSTART and found the following.
1. If your DESKTOP.INF file includes any OPEN WINDOWS on the
desktop, then the current working directory will be set to the uppermost
of them. (just like on the desktop!)
2. Otherwise, the current working directory will be set to the
root directory of the boot disk.

I'm not putting down Lyco, or any other mail-order outfit, but you should be aware of a potential problem with buying Ataris by mail. Atari's warranty is enforced by the dealer from which the computer is bought. This means if your new ST coughs and dies you have to send it back to Lyco (or whoever) to get it fixed. If you take it to a local Atari dealer they will charge you full price, which is at their discretion to set. So beware.

>to do right away if he got a 520).
>

Yes, I have priced software. And as a matter of fact 80% of it _requires_ at
least a meg. This I knew already which is why I wanted the 1040. Also, I
intend to make all the hardware modifications there are possible, and it is
much better to *start* with a 1040 than to end with one...

In any case, I ordered one. When I talked to CMO the first time the operator
said they expected them in next Monday (translation:15 to 20 days), that is
the best date anyone gave me, the price is the best too(even though it is $200
more than I thought I would pay 3 months back-BLAME THAT ONE ON THE COMPANY
WITH THE INITIALS A.T.A.R.I.), so hopefully I'll have it _by then end of the
month_ for $1004.

Stay tuned....

Firstly, this is meaningful only to those who know what are the values of NFATS etc., which does not include me! My hard disk has the bootstrap of HDB version 2.3, and nowhere in the first sector of each partition do I see any corresponding values (trash or correct). However, PCDITTO fails to recognise that I have any hard disk at all, whatever I try.

>(Oh, BTW: where in the world am I supposed to get HINSTALL and SH204DVR.SYS,
>the official (?) Atari HD boot stuff? The SH204 I bought was shipped this
>fall with only AHDI and HDX. In contrast, Supra supplies a very nifty HD
>sector editor.)

Same question. I got mine ages ago, with AHDI and HDX. Had never heard of HINSTALL and SH204DVR.SYS. Are these necessary to recognise the hard disk?

Another question re PCDITTO, which I bought (pause to polish halo) from England. The docs I got claimed that it was not the same as the US version, but actual use shows that it still has a hard-wired US keyboard: not too different from the UK one, but annoying. Unlike Gulam, it does not appear to have the mappings for physical key to character, but it does have some tables (256 bytes long: sounds familiar) which might have some effect.
Plea to US writers: please remember that there are different keyboards, including extra keys, plus foreign characters which require 8 bits in Atari internal character representation.
Plea to European/UK people: has anyone figured out how to modify these

tables in PCDITTO.

Entirely unrelated subject: does anyone have a copy of bootmakr.prg, as I want to be able to automatically start UniTerm AFTER running gemboot.

This will happen also if you have formatted your disks with the original version of TWISTER. It never changed the serial numbers on the disks!!

If you have the original, call a BBS and get the one called TWISTE.PRG (usually). A patch is also to be found....

Concerning the enthousiasm about the speed of Tempus:
There is a faster and much more versatile editor on the market nowadays:
It is called STedi and is sold as part of a development package called
Craft which contains the GPshell: a UNIX-like shell, STedi and a number
of utilities like make etc.
The package is made for people who are involved in making larger programs for
whom the speed and versatility is very important.
Compared to it Tempus is merely a toy.

I don't know if this is entirely correct, but since no-one else has answered you,.....

I believe that the 40 folder bug is due to the memory management bug in TOS (or whatever). It appears after you open a non-deterministic number of folders (~ 40) during one session (ie. between resets or power cycles).

I think this is correct.. maybe someone will give the definitive answer.

This would be really good news if the C compiler that Atari is distributing now with the developers kit was the MWC compiler with the debugger. Has anyone received the new developer kit? Can anyone from Atari give us some info here?

Also, if anyone sees this, it would be interesting to know if the debugger can work under gem-aes. That would seem to be a much harder nut to crack.

Dave B.,
By offering a free RTX it would be possible for you to sell the information reguarding it. Such as programmers guides, user docs, etc...
Also, maybe developers could pay to use the shell in their applications. Maybe I don't know what I'm talking about (I usually don't). How about a shareware type RTX.

>Atari ST to SCART adaptor in early 87 (march I think). SCART is an
>analog RGB interface with composite sync - I think this should do what you
>need. Parts cost is under $20.00

The Atari ST to SCART adaptor sounds interesting, but would it provide BOTH rf & composite? Remember that the adapter that I described earlier (from Practical Solutons) is targeted at those ST's without rf OR Composite signals available (most 1040STs, some 520STs).

The primary advantage to the device from Practical Solutions, at least in my mind, is that an individual with a monochrome 1040ST system would be able to hookup to a color (colour for the Europeans on the net) TV vs spending $350+ for a color (colour) monitor.

The secondary advantage is that, if desired, owners without rf modulators, again (most 1
video capture of their sessions/games (really handy for maze-type games <after you are killed off go back and replay the tape, pausing the VCR at critical points as you draw out a map of the maze. >

Both the primary & secondary advantages I mentioned above require RF signals. As described, it's not clear that the Atari ST to SCART adapter would provide RF.

On a related note:

A word of caution, there are cables advertised that "CONNECT YOUR ST TO COMPOSITE MONITORS!" (i.e. E. Arthur Brown Company, pg. 56, of the Winter 87 Issue of STart) for only $14.95. But these will NOT work on an ST that doesn't have an internal RF modulator (most 1040STs, some 520STs).

Source record: 254615

Last word I heard from E. Arthur Brown company was that they had stopped taking orders for the ST Video Box and were refunding money for orders that had already been received.

According to their explanation, when they started bench testing the ST Video Box, they found that it would consistently "burn-out/ fail" after a couple of days use. They went on to apoligize for not adequately testing the product before starting the Ad campaign. The inventor of the ST Video Box is, according to E. Arthur Brown company, in the process of investigation/re-design of the circuitry involved.

If anyone has heard that a new/improved ST Video Box has been released, please let me know.....

> solved?

Try Mark Williams C. It has long variable names and enums as well as
structure passing, large arrays and functions, and accurate floating
point. If you put MWC's /lib and /tmp directories on a ram disk
(needs 1 meg to do this) the compile times are close to MegaMax. And
the new (version 2.1.7) manual from MWC is one of the better resources
for programming on GEMDOS/TOS that I've seen.

NOTE: I am a beta-tester for MWC, so my opinions are somewhat biased.
I became a beta-tester for them AFTER buying 3 other C compilers for
the ST and getting burned every time (including MegaMax).

There is not a 'fix' for the problem since that is awaiting the LONG promised rewrite of GEM but there is a program FOLDRXXX.PRG that patches around it which amounts to almost the same thing and will have to do until the world ends or Atari releases a new version of the OS, which ever comes first (semi :-).

This is a complaint about the 'protection' used by one author for
his shareware product:

> Perhaps the worst I have ever seen of this type is a program, DS, a
> progam to help move, delete, copy, etc. files on hard disks. While the
> program was quite good, and the request for money was small ($15), the
> program had a 10 second delay at the beginning and the end of a run.
> Instructions for disabling this pause were available only after you
> coughed up the $15. This, to me, is a type of blackmail. Since the
> use of this program is to be a quick utility that works faster and
> easier than DOS commands, a delay like this was way out of line.
> Needless to say, I don't use the program, and would never suggest that
> anyone else do.

I am impressed with the method used, and am surprised at the audacity
of the above user. The author has found a very clever way of
protecting his SHAREWARE product, which allows a user to sample the
product, yet requires an end-user to pay IF and only IF he/she intends
to use it regularly.

:-(

Hmmm. I can get the MW c compiler for $175 from MW. Dev docs for
$100. 175+100 = 275. This means that atari makes 25 dollars for
nothing.

Wake up atari we are not that stupid.

Some may argue that the $25 is beeing used for support. Well the $25
will not be worth it until we see some support.

:-(

1574. Re: GEMDOS History

Newsgroup: comp.sys.atari.st
Date: 1988-02-04 17:23:43 UTC
From: mj@myrias.UUCP
Message-ID: <551@myrias.UUCP>
Source record: 254624

Bruce Holloway gave us his version of origins of GEMDOS. One would
really would like to believe in all these stories about one mythical
evil system programmer. There is only one fly in this ointment. DRI,
as I understand, is responsible for a lot of other "goodies" on ST.
Let us see. First GEM itself. Is also full of bugs (should I include
a well-known list). It does practically nothing else but puts slow and
unwieldy graphics shell on the top of your computer. This shell has not
a slightest clue what is a search path, environement variable, etc. Can
handle one file only at a time (with an exception of copying - but pray
that you do not have grab more files then slots in a window). What is
more GEM was crippled from the very start because of missing integral
part - an infamous GDOS. Therefore no proportional fonts, no device
independent output, no (actually) multiple virtual workstations. In
other words - nothing from all these things for which one really suffers
and learn to live with cutesy, SLOW, graphics interfaces. You may
continue this story on your own.
Ok, wo what else we got from DRI. Well known Alcyon C compiler in
which nobody bothered to fix even such simple things like error values
returned from every pass. Accompanying "documentation" and tools were
of similar quality. A recent message from Neil Harris indicates that
currently Atari values Alcyon C for $20, which seems to be generous.
This was followed by the next DRI product included with ST, namely
Dr. Logo. Probably one of worst Logo implementations which I ever
seen. Both buggy (it rally cannot handle any more involved recursion)
and, once again, awfully slow. Logo on 1MHz 9900 (TI99/4a) is much
faster and better done then DR.LOGO on 8MHz 68000. Though the first one
is a little bit more cramped, due to somehow smaller memory available.
DR.LOGO is also no good for anything else, but some turtle play (if you
are really patient). Reason - even rudimentary file access was
conveniently forgotten.
This LOGO was also graced with an editor which can be overtyped by a one
finger typist. I guess that one has to write it in interpreter written
in slow BASIC to achieve that effect.
The only redeeming feature in all of this is ST BASIC. It was so
awfull, that nobody wanted to use it at all and everybody switched
immediately to other languages. It this was a part of a master plan to
force good habits onto microcomputer users, then it succeded
admirably. Only I am not sure if DRI was responsible also for that.
If all of above was one-month doing of a busy system programmer, then
this guy, for sure, had a quite hot month.

>
> This is a followup to the discussion of offering a free run-time
> multitasking kernel to all Atari ST users.
>
> So let's hear those arguments for a free RTX. Don't take that as

I may have a few misunderstandings here, but here goes anyways.
Anytime I say something stupid/incorrect, please correct me.

My understanding is that the Beckmeyer multitasking Kernel will not
run many (any??) of my favourite programs. Eg.
Uniterm
MicroEmacs
Gulam
MWC
There are also many utilities that came with MWC that I assume I can
recompile to run with RTX so they shouldn't be any problem. However,
the above systems/programs are the ones that I need to run
simultaneously. If I am wrong about the above programs, tell me and
I will be off the to store right now!!

What are the problems with these programs?? (or ST programs in general)

GEM Calls??
Screen requirments??
I only have 1 screen/terminal to use, and each
standard ST program also needs its own screen. On
the Amiga this is solved by having all programs
designed to run in windows. The user decides what
size and where the window should be put. This is
not possible with the ST: All the programs have
been written with hard-wired assumptions about
screen size and location. Obviously, we cannot take
the same route as the Amiga. I see several
possibilities:
Have multiple screens, some way of switching
between them, and some way of displaying the
fact that a background window has changed in
the corner of the foreground window.
(eg. DiskBar or CornerClock type info)

Divide the screen into 4 equal parts, each
one devoted to a process/program. Again,
each program has its own screen ram, and any
sub-screen can be expanded to full screen

width. (I would be happy with 4 progs...)

I would like feedback/comments.

Jeff,

There are at least two different work-arounds that patch a larger number of memory buffers into the system. These are kludges that provide a larger number of folders, but there is still a limit when using these methods. This is not what I and most other users call a fix to the problem. A real fix is being developed at Atari and will hopefully be available sometime in the near future. Near future in this case probably means a year. In the meantime, you should use foldrxxx or GEMBOOT in order to get around the 40 folder problem.

I should also mention that the new release of ROM's should have numerous other fixes such as the Malloc problems, etc.

I hope this helps.

Barry

OK -- Here we go...

We have had a lot of experience here at Planetary Science buying
ST lately...they make great pieces of lab equipment. One of the
people here at the lab recently (Dec) bought a 1040ST thru Lyco.
He payed a great price (around 650 for mono). Now in January another
fellow in the lab decides to get a 1040 from Lyco. Current cost: $850
What happened? Well, sources (from within Lyco and other mail order houses)
tell us that Lyco had been getting its STs "illegally." Atari found
out, and now if you try and order from Lyco, their costs
are the same as everywhere else, and you have to wait three months.

What does "illegally" mean? Your guess is as good as mine.

Consider yourself warned.....

Hello World,

I just bought the ST Replay cartridge from 2-Bit Systems, and I am
pleased with it in general. I also purchased Digidrum for it which made
it extremely nice for use in my home recordings.
My question is, does anyone know of ANY software out there that uses
the Replay cartridge other than the stuff that comes on the enclosed disk
and the Digidrum package? I heard rumours of games that used it for
awesome sound but none of them have materialized. I heard a rumour about
a program that would accept a MIDI keyboard input and play back the
samples as if they were being played on the keyboard. But I have seen
NONE of it! Names of programs and their publishers would be greatly
appreciated. If anyone cares, I could summarize to the net...

> you can do whatever you want. If I remember correctly this is described
> in the Atari GEMDOS Users Guide manual.

Not exactly. First, GEMDOS calls the "terminate vector" not the
"critical exception handler." Second, that vector points by default an
RTS instruction. It is the code after the call which terminates the
process.

This vector gets called when you use Pterm(), too: it's not strictly a
"control C" handler.

You can avoid being terminated by doing a "setjmp(term_buf)" where you
want to recover, and setting this vector to point to something like
"longjmp(term_buf,1)"

Unfortunately, there isn't a lot of documentation on this, and other
projects prevent me from going into more detail.

Having disassembled gemstart recently, I'll describe what I found out.

It installs a VBL routine (in slot 1, not checking if it is in use)
that waits until the line-F trap handler is initialized (changes).
GEM uses the line-F opcodes as a "short" procedure call.
It wraps it own line-F handler around GEM's handler,
which intercepts two line-F opcodes (I don't know what they are).
When the handler encounters one of these opcodes, it looks up an address
in the ROM relative to the caller's PC, and uses that
in some way to pass the name of a program to be started by GEM.

I wish people who write this type of program would distribute
source; the programs are bound to break with new version of the OS.
I guess someone will have to disassemble gemstart and try to fix it.
(not me, I don't have an assembler)

1584. Shareware? Hah!

Newsgroup: comp.sys.atari.st
Date: 1988-02-05 02:25:11 UTC
From: peter@nuchat.UUCP
Message-ID: <622@nuchat.UUCP>
Source record: 254634
Cross-posted to: comp.sys.amiga,comp.sys.misc,comp.sys.ibm.pc,comp.sys.mac,comp.sys.atari.st

I wrote one shareware program.

It was a terminal program called "Smart TTY", for the PC.

It supported simultaneous file transfers or interactive sessions on both
serial ports. It never blocked I/O to the screen, so you could see *what*
the weird garbage you got from your port was (like "File Transfer Aborted"
or "You have 5 minutes left" :->)... anything that wasn't a packet was
displayed. It wasn't a speed demon, because I used the BIOS for maximum
portability, but it could handle 2 1200 baud lines at once through the use
of crufty heuristics and careful screen updates (my early efforts in writing
a curses wannabe back before Ken started letting other machines than Cory
EECS 11/70 use it helped). Just Xmodem and Xmodem CRC, but good emulations
of Vt100 and ADM22 terminals. Pull-down help screen and setup menus. Drag down
screens (really! You could drag down session on COM1 and see what was going on
on COM2). Intended as a tool for people calling up VAXen and their ilk
from a PC.

I asked $35 to get an update and remove the startup message that read:

"Send $35 to stop me printing this obnoxious message and to
get an updated version of this program"

or something like that.

I got 3 letters from people wanting me to add features before they'd send
their $35, and one guy claiming he wanted a free copy for a review. Wouldn't
say what his magazine was.

Shareware, hah!

1587. Laser printers

Newsgroup: comp.sys.atari.st
Date: 1988-02-05 09:28:00 UTC
From: GASPARD@HROEUR5.BITNET
Message-ID: <8802051012.AA09638@ucbvax.Berkeley.EDU>
Source record: 254637

>First - does it make a great deal of sense to by the laser engine for
>$2K when right next to it is an HP going for $1.7K, which has .5 Meg of
>memory, and the ability to upgrade it to almost anything. (Postscript
>included). Is the quality of the Atari Laser so great as to outweigh
>all other factors?

You're right. The HP offers more value for money.
Output quality of the HP LaserJet II is among the best in small laser printers.
Very nice blacks etc. The fundamental difference between the HP and the Atari
engine is that the first is a so-called write-black and the Atari is
write-white. Write-white has a theoretical advantage when it comes to
printing large black areas. Write-black is better for fonts though, especially
at the 300 dpi resolution of these printers.
On the whole I doubt you'll see a lot of difference between the output of these
two printers.
The HP has easier maintenance. You replace one cartridge every 4-5000 pages.
No messing about with (nasty) toner. The Canon-engines of the HP have built
up a very good reputation in terms of reliability.
The Kentek engine of the Atari laser is used by Oasys for its laser printers,
which, by the way, are even cheaper. But I have never heard about any long-term
experiences.

>
>Second - consider the following two scenarios. I buy a mono-mega4 and
>an atari laser printer for $4.5K, and lets say Word Perfect, a page
>publishing program.
>
>-or-
>I buy a mono-ST for .9K and a AST Turbo Laser for $3K -> for a total of
>$3.9K.
>I have the same software.

The AST has a major advantage; it supports Postscript. This alone, I feel,
makes it a much better choice than the brain-less Atari laser. Everybody
supports Postscript these days. You can safely assume that it is the standard
for the next 3-5 years.
The AST is based on the Ricoh engine. And I found none of the Postscript
lasers based on this write-white engine (e.g. Texas Instruments 2108/2115,
Digital Scriptprinter) to have very satisfactory output. Every font looks
bold.
The Postscript option on the HP laserjet II involves a board for a PC. You
won't be able to use it with any ST in Postscript mode.
The Postscript language (but not the Adobe fonts and font-manipulating
algoritms) is in the public domain. With 4 Megs of memory it should be
possible to implement the Postscript RIP in the Mega ST and send the

page bitmap to a dumb laser printer such as the Atari. But I have yet to hear of anyone announcing such a product. I'm afraid the market may not be large enough to make it interesting.

I faced exactly the same dilemma as you are in three months ago. I ended up buying a NEC LC890 Postscript laser (approx. $ 3.3k, also 3 Megs of memory, write-black, two paper bins standard, etc). Apart from the fact that there is still no satisfactory desktop-publishing software on the ST, I also wanted to print from a PC (using Ventura Publisher; when are they finally going to port that to the ST?). And, most important, Postscript files can be sent to a typesetter; I don't think Linotype or any other mayor supplier of typesetting equipment has plans to support GDOS. Let's face it; even Atari hardly supports it.
And I must agree with other owners of the NEC; you'll never want any other printer (except of course that 2500 dpi colour laser for $ 2k). Apart from Postscript (with all the LW+ fonts) it offers HP LaserJet and Diablo 630 (very useful for program listings) emulation.

Has anyone managed to print to a Postscript printer (such as the LaserWriter) with the Magic Sac? Serial communication is no problem, but how does the Mac Postscript driver behave with the ST?

If you want more info on laser-printers join Laser-lovers, Postscript and/or the Desktop Publishing list.

Please correct me if I'm wrong, but I believe that in RFC 822 (I don't have
a copy at hand) it states that the error returns will go to the "Return-Path: "
header. So, wouldn't a field such as

Return-Path: <info-atari16-request@score.stanford.EDU>

alleviate the problem of errors being rebroadcast over the network? Maybe,
BITNET can't handle such headers; otherwise I would suggest that the return
path on BITNET would point to the Redistribution Manager on BITNET.

==========

TEXT OF CONFERENCE ON DELPHI REGARDING ANALOG BUYOUT
JANUARY 17, 1988

Andy> I'd, first, like to welcome all of you attending this conference. My
name is Andy Eddy and I'll be moderating the CO.

Lee> First, ANALOG has signed contracts with a publishing company in
LA. That company is LFP, Inc....Larry Flynt Publishing. We expect to have
the next issues of both mags out in 3 weeks. Let me give a few words about
the changes...First...Larry Flynt has little to do with daily operations of
the company...as a whole. He will have nothing to do with the editorial
contents of either magazine. Changes you will see include new (glossy)
paper, a heavier stock inside as well as a heavier cover. More color pages
throughout, INCREASED distribution, Much improved service, and a steady
frequency. What you won't see is ads for Hustler and the like.
LFP, Inc. also publishes a Mens fashion mag, a running mag, a new
automobile mag, a motorcycle pub and a Heavy Metal mag. With many more non-
pornography titles on the way.

Andy> Thanks, Lee. So the fears..that this will be anything like..Hustler
will not materialize. This will remain the same Analog as before..but
with some changes in the "production" end..not the editorial.

Lee> OK. There WILL be changes.. Because I won't have to deal with such
things (as much, anyway) as distribution...subscription problems, and
production, I can spend more time on editorial...that goes for Clayton as well.

Andy> So you don't see anything but beneficial changes for the mags?

Lee> Actually, let me say this...the only way someone will know we are
owned by another company is a small blurb on the staff page. As far as
changes go, I expect an even more steady stream of quality editorial
since it will be the main direction of our time working on the mags.

Maurice M.> Okay. I want to get this subject out of the way now especially
in light of recent messages in the forum. Certain people have hinted that
there will be changes in the magazine because of whom the ownership is. The

point, I think has been refuted. However, DF Scott has in recent messages hinted that several of us writers were in a "dilemma" over the ownership change and might no longer write for ANALOG. I would like to put to rest any fears readers might have about mass-defection of writers by asking you, Lee, if you are aware of any other regulars "leaving" because of this ownership change.

Lee> No, not at this time. Let me respond to your comments. While I don't whole heartedly agree with Larry Flynts views. I am looking at what that company can do for our magazines. They don't know ANYTHING about what we publish, they (LFP, Inc) are leaving us alone in what we do. To them profit is what they want, editorial content is 100% up to what we do. They'll make the magazine look better, distribute it better, and put out a quality looking product, it's still up to me, Clayton, Maurice, Charles Johnson, Andy Eddy, MAtRat and the rest to put out a good magazine in product. To answer Maurice's question, other than Scott, no one has more than batted an eyelash over the buyout in terms of who it is. After the initial shock wears off on the buyer's name, they settled in and want to get back to work.

Maurice M.> Good to hear. I simply wanted to address the subject because I wanted people to be aware that Scott didn't speak for all of us. I'll step down now.

Lee> Last Monday is when Michael Des Chenes and I signed. We are waiting to get them back from LA now then it will be official.

Clay> Anyone who is interested in the terms of publication and how to submit articles may send me a self-addressed, stamped envelope and I'll see that you get our writer's guidelines. You can send requests to the PO Box 23 address in the magazines for now.

Andy> Also with Analog's liberal policy of letting programs go onto BBS's after 1 month from issue date (that is right?), everyone gets to see the stuff they publish.

Clay> Yes, Andy.

Mike Brown> Will we be able to get back issues of both magazines and disks as in the past? Or will these "Classic" issues become collectors items?

Lee> Yes! LFP, Inc is purchasing our entire supply of back issues. Including disks, 8-bit Extra's and so on. We expect to offer disks at a lower price and the availability should be MUCH better.

JIMGAR> Thanks. My burning question is WHY???? Wasn't Analog a profitable venture?

Lee> WHY is a complex question. First - WHY NOT? ANALOG was myself and a partner, Michael Des Chenes. As you may have noticed, Michael never spent much time on Delphi and while I have gone to over 100 Atari shows and ComDex's, etc., he has not. Michael has been bored doing the same thing for 7 years and wants to try something new. In addition, I couldn't see the company growing much further the way things have been, so this gives us a

chance to expand greatly....plus I'll be working on new publications, both computer and non-computer related in the next few years.
Also, LFP, Inc. offered us a very good deal...and who really knows how long Atari will keep going. This way I can expand on my interests and do other things along with the Atari field -- after all, I have been doing the for 7 years. A long time!

JIMGAR> In other words, the whole thing got out of hand?

Clay> A company can only grow within the facilities it has at hand.

Lee> Right...We needed to expand, and as do airlines, insurance companies and so on. We were bought out to expand our capabilities.

WHITEWIZARD> you said that the analog depends on the 8-bit...Does this mean that you might stop publishing in the future if the 8-bit fails (ANALOG, not ST-Log)?

Lee> ANALOG depends on the 8-bit market ...Lets say that advertising right now isn't overwhelming and ANALOG would most likely take a new heading (orientation) in the event 8-bits REALLY dwindle. I could see a change happening probably this year some time...

WHITEWIZARD> Would you combine ANALOG and ST-Log again?

Lee> Again, it is mostly up to the ANALOG staff, not LFP, Inc. Yes, I could see us doing one mag--but here is the problem. The ANALOG name is the best known, if we put in ST-Log then the mag becomes a general Atari mag again. If we kill ANALOG and continue ST-Log...well ANALOG has the more known name and that would be a mistake. Chances are ST-Log might have some 8-bit coverage...but that is all up in the air right now. When we are in place after a couple months we'll look at the whole picture.

MADMODIFIER> With many software publishers spreading out to the Amiga..... Is there any chance that Analog might do the same?

Lee> I have plans to do another computer oriented mag but can't say much (exactly nothing) about it.

MADMODIFIER> You mean we might see AMIGA LOG <grin>?

Lee> No Comment. But I hope to have a new project out in late Spring.

Mike Brown> I would like to suggest that you run some type of a readership poll in your first new issue to determine what your readership looks like now.

Lee> Huh...in what way? Between ST and 8-bit?

Mike Brown> Well I imagine that the complexion of the readership has changed somewhat. It might be worthwhile from a marketing standpoint.

Lee> You mean between 8-bit and ST??? Sophistication?

Mike Brown> Well that and just what people are interested in reading about. What their needs are "today".

Lee> We have the "bingo" cards in the mag every month and poll those to see what people are using...however we have talked about doing another mail-in campaign...a more in-depth look. Remember that Delphi users are more into their machines than many other average users.

Mike Brown> Maybe, but I guess my point was that at least in the 3 user groups I belong to things are in a state of "change".

STeve M.> What direction will ST Log be taking in terms of content? General readership, programming, or what?

Clay> I can't see much that will change in ST-Log. Is there something you WANT to see changed?

STeve M.> No, just was hoping there were not going to be any drastic changes now. Thanks.

Lee> I feel we have a good balance of information, sophistication and programs. I think Clayton, myself and our new west coast person will have more time to look at each issue well in advance and look at it's contents to see what blend of information it has...thus boosting the magazines quality...(not that it needs boosting <grin>) in addition, hopefully we'll add more pages too.

Clay> The combination we've had in the past has worked out well, I think. I don't see any reason to change it. (More pages would be nice.)

Lee> No, I certainly haven't seen any complaints about the balance of material. Keep in mind that I'm moving from New England (fresh air, no traffic, nice scenery) to LA (smog, Lots of Traffic and more smog) for the CAUSE. In other words...If I didn't see a tremendous potential in this I wouldn't do it!

1590. Re: Free RTX (or maybe almost)

Newsgroup: comp.sys.atari.st
Date: 1988-02-05 14:08:27 UTC
From: cyliax@ea.ecn.purdue.edu

I'm all for a free or inexpensive RTX, as long as we can get enough
docs and information to be able to port/run our application. Does
this operating system imply that it will be TOS compatable, i.e.
will compilers and things that we have accumluated still run under
it ? If it does it certainly seems a better solution that os9 or
waiting for Minix. I don't mind spending a little money for this,
say < $75 bucks, but if it's more than that, I probably wouldn't
bother with it. Considering you could get real UNIX for PC's
for less than $200 from Microport, I would probably just sell the
Atari and by a PC (yuck....) with UNIX.

So I guess my point is that if it's < $75 or so but you charge
enough to provide good docs. and support, I would probably buy it.
I would even pay more, if it comes with a decend "C" development
system and other tools.

>>
>>Do you have a 'GDOS'-printerdriver for the AST-turbo-laser?
>
>Who cares - I haven't seen GDOS out of atari yet and I won't spend $2000 to
>get it.

GDOS comes with ATHENA II from Iliad Inc., ATHENA II is a CAD program,
and it uses GDOS for it's output to different graphics devices. They have
some drivers for things like FX-80's and such, but they don't have any laser
drivers... I would love to get my hands on some more info about GDOS,
like how to write device drivers and the like. Ultimately, I would like
to have a driver for Postscript Printers so I can run stuff off on a
variety of Lasers. So, as soon as I find out more about GDOS, I could
get started on writing some device drivers, which I would probably
make available to anyone who wants them.

B.T.W., ATHENA II is a pretty decsend CAD program for the price,
it's only drawback is that there aren't too many drivers available for
hardcopy devices. It's not as good as some of the packages available
for PC's, but then it's also a lot more inexpensive.

Once a week we receive an enormous amount of news from the United States.
It is sometimes interesting to read some of the newsgroups. However, it
is extremely annoying and timeconsuming to read messages which do not
belong in the newsgroup in which they are posted. This the case with the
endless series of messages on the subject of software copying.
I urge on those who posted them not to do so in the future. So, please,
when you flame on the subject of software copying, reduce your newsgroups
to which you post your messages, comp.sys.misc seems appropriate to me.

Whishing not to hear from you again,

Olivier van Wijngaarden.

P.S. At least, don't post them to comp.sys.amiga.

1593. Mega Compatible?

Newsgroup: comp.sys.atari.st
Date: 1988-02-05 15:46:59 UTC
From: Flash@UMass.BITNET
Message-ID: <880205103031DE1.AVLQ@Mars.UCC.UMass.EDU>
Source record: 254643

After having a long series of programs bomb out on our MEGA ST2 here at the store, we decided to do a little testing. We copied the ROMS in the Mega (to make sure we have the SAME version) and placed them inside a 2.5 meg 520. We then proceeded try out some software that crashed on the MEGA.

MEGA ST2 520 (with 2.5 MEGS and SAME new roms)
-------- ---------
Gaunlet CRASH! Ran great!
Eagle's Nest CRASH! Ran great!
A-Calc Prime Some Prob. Same.

And the list goes on...

Ending result? It seems that 40% of all the programs that have problems with a MEGA work fine on the 520 system.

What does this mean?

That something fishy is going on with Atari. They claim that only the ROMS changed and that the hardware is the same (appart from an invisible blitter).

Well, obviously it is not. NEW roms are not was is making things non-compatible instead something else is, something having to do with the MEGA design.

Our Atari Representative was simply as baffled as we were...how comforting.

On a related issue, our store has been experiencing a 50% failture rate with the new mega's. Just thought that was most interesting.

BTW, we got in the TECH SPECIALTIES 2/4 MEG upgrade board for 1040s. DO NOT BUY THIS UPGRADE. It does *NOT* fit in a 1040, and the instructions are WRONG. If you cut the trace that they as you to, you DESTROY your MMU when you power up, as a poor customer of us discovered. (all taken care of now)

If you want to go to 2 or 4 megs and you have a 1040, wait for the AERCO board, which should be shipping as I write this..(hopefully)...they have worked on it for a long time..are aware of all motherboard revisions, and basically have their act together.

GUNSHIP is supposed to ship in the next couple of weeks, and those who have seen it say it is hot, watch for that one.

Anyone know when LASER C is shipping?

Anyone know what is the deal with Data Pacific. They are starting to remind me of many mail order places I love to hate. This is what is happening.

I called 3 months ago and ordered some MAGIC SAC PROFESSIONALS. I asked the lady on the phone "Are they in STOCK and shipping?!?!?" She said "Yes, should go out tommorow."

To make matters short, 3 months later, we have seen nothing, and we call them EVERY week...and EVERY WEEK...they tell us..."Just shipped." Gets kind of fishy after the 6th time.

Talked to David Small on GENIE who promised to look into it, since he is also claiming that they are shipping. Never got a reply.

Annoying part is, that this stuff was/is for a goverment BID. You know how those are picky on product delivery. Well, we are still waiting...nd in

1594. New ARC somewhere? - (nf)

Newsgroup: comp.sys.atari.st
Date: 1988-02-05 16:26:00 UTC
From: kirchner@uklirb
Message-ID: <4300005@uklirb.UUCP>
Source record: 254644

Hello Netlanders,
has anybody seen a newer ARC than the one we are using now (is 5.12) ?

Why I ask: I collected some arc-ed files from the pc-bin-group to be run
on a collegue's PC, and most of them I can unARC with ARC-5.12 without
any problems. Now I got some, where ARC says it cannot unARC and :
'perhaps you need a newer version of ARC?'.

In the PC-Group they speek about something called ARC 5.2.1, PKARC,
PKXARC etc. I also have read somewhere the term 'squashed' for an
even higher compression then 'crunched'.

So, if somebody has such a newer version of ARC: Please post it to
us all(ARCed in the OLD way !!). If possible please post the source
also, so we can install it on UNIX-Machines and can download binaries etc.

Thanks to all Super-ARCers

>> The base page does not contain any backward pointer, so what is it ?
>
>I'm not sure that MSH does* detect being called from the desktop. What
>difference would it make (or does it in MSH). The basepage, however,

When msh spawns another instance of itself (e.g., msh starts EMACS which spawns another copy of msh) is does not read the profile file. I presume that this difference in behaviour is why msh has to know where it came from.

It also does not inherit shell variables (it does, however, inherit environment variables) which means that commands defined in the .bin or .cmd pseudo-directories are not available in 2nd (and subsequent) copy of the shell.

>PS. For those waiting for dLibs

Does dLibs or any other public domain library contain a version of "regexp"?

1596. lockup -- mouse lock & infinite key repeat -- Help!

Newsgroup: comp.sys.atari.st
Date: 1988-02-05 16:53:01 UTC
From: jpdres13@usl-pc.UUCP
Message-ID: <826@usl-pc.UUCP>
Source record: 254646

Eeeeeargh!

Last night while computing away I had the wierdest thing happen, my keyboard just started sending a stacatto rush of keypresses to the computer and my mouse locked up. The minute I turn on my 1040ST I hear the sound of a key repeat, it does not let up at all unless I happen to stick in a disk that has a desktop.inf file that wants to access a window on drive b and I have drive b turned off. I get presented with an alert box that says "Insert disk B in drive A" , you know, you have all seen this one. Anyway ... the sound stops and the mouse is frozen, I cannot even hit return to bump the default "ok" exit button in that alert box.

In this state I wait for some advice from the experienced users of the net.

I suspect the keyboard controller chip, since polling the keyboard and the mouse can be done with event_keybd().

If you have any experience with this problem , please let me know about it and any solutions that you might suggest.

I think that I will try to reseat some chips tonight, as that seems to be a popular fix suggestion from Neil Harris.

Incidentally I have 1040ST #000000054, or , number 54 in the first batch of 1040's out , in case anyone knows of such a quirk in an early series model.

Thanks for any help you can offer.

Source record: 254648

I don't know RTX but if it is any good (as the majority of
articles say) then I rather suggest that Atari *BUYS* the
RTX multitasking system from Beckemeyer and releases it then
into the public domain.
Making the ST a more workable computer should be the task of
the manufacturer and not the burden of (small) independent software
companies. (Just _somehow_ I doubt this will happen...)

It should be in the public domain, so that software companies
can write software for RTX and provide RTX with the software.
Else the conservative company will keep on writing TOS appl.

I hope someone at Atari will step forward and give their position
on this issue.

This is again NOT a flame toward Alan.

Jeff Chiu

Atari: just because other people put their system into ROM, it doesn't
mean that *yours* is qualified to fit in there.

1601. How compatible are MS-DOS and TOS disks, REALLY?

Newsgroup: comp.sys.atari.st
Date: 1988-02-05 18:13:00 UTC
From: goldstein@aim.dec.com
Message-ID: <8802051651.AA00683@decwrl.dec.com>
Source record: 254651

Weird stuff.

Okay, I've read it a thousand times. MS-DOS disks are formatted like TOS disks, the only difference being the MS-DOS boot sector. So I can exchange files freely, right? Well, usually, but sometimes it gets very, very strange.

Take this nice, shiny SONY MF2DD sitting next to me. I formatted it on a NEC Multispeed (MS-DOS 3.2), labeled it, and used it for some MS-DOS work. Fine. Then I used MS-DOS Kermit to move a couple of ARC files, one an MS-DOS ARC and one a TOS ARC, to said diskette. I took it home to the 1040STf and copied the TOS ARC to another disk for de-arcing. Fine. Then I did some work and copied a text file back to same disk so I could read it on the NEC as well. Lo and behold, doing a DIR on the Atari (both GEM desktop and using PCOMMAND shell) showed only ONE file on the disk, that being the one which I just put there! So far as the 1040STf is concerned, all the other files on the disk are gonzo. Todt.

So I take the disk back to the NEC and do a DIR, and lo and behold, the old files are still in the directory! But not intact; looking at an old TXT file I see the new one (Atari-generated) and the old one (NEC generated) intermingled. Yep, the Atari overwrote sectors used by the NEC. It really didn't see the directory.

It sounds like I have to restrict my floppies to being written only by one or the other OS. I can format on MS-DOS and read/write on Atari, but if I want to write under MS-DOS I can't write to the same disk with the Atari. Boo hiss. Anybody understand what's really going on? thanx.

1602. RTX, MT-C shell, TOS compatibility?

Newsgroup: comp.sys.atari.st
Date: 1988-02-05 18:23:00 UTC
From: goldstein@aim.dec.com
Message-ID: <8802051700.AA01475@decwrl.dec.com>
Source record: 254652

Dave Beckemeyer's comments recently have been interesting. Before I even bought my ST in 1986, I had asked around about multi-tasking options, and saw MT-C shell. But not having a hard disk and not being a "unuch", I didn't really have much use for it.

Now he generously suggests making Micro-RTX, the multitasking back end, free. This would allow software developers to write to a "standard" method of multitasking (where "standard" means "the one that's free so everybody can use it"). And, I suppose, he could still _sell_ both the developer's kits and MT-C shell. I sense a nice business plan here: Give away the back end and get enough volume to sell the rest. If I were in his shoes I'd probably figure it's worth a try.

But that gets down to my real question: How much of TOS is really replaced by RTX or by the other BDT products? It sounds as if they really rewrote TOS into a multi-tasking OS. If that's true, and if it really will run existing software (my 40-odd floppies of applications; I'm not a developer), then it may be worth paying for. Just to get the original's bugs out!

So, will MTC-shell and/or Micro-RTX do the following?

MTC RTX

Run existing non-GEM programs, like MicroEmacs?
In the background?
Run exisitng GEM programs, like Uniterm?
With others in the background?
Switch between GEM programs?
Switch between non-GEM and GEM programs?

What limitations are there? Thankx.

I don't recall D. Beckmeyer ever offering to put his shell
in the public domain, only the multitasking kernel (RTX).

However, if he does make RTX public domain or cheap
(15-30$ for binaries, no doc.) I suspect several people will
add job control to PD shells, and DlibS will probably get fork().

I went into Federated last night and saw Microsoft word. There were no salesmen about (not like Federated, where you are usually harassed by three at a time! :-) so I opened it and looked inside....

Well, it comes with a GDOS disk and three fonts for those with enough memory or a GDOS supported output device (EPSON and ATARI Laser Printer right?)... So GDOS has emerged from the depths of rumours and bad licensing agreements, eh?

Microsoft Word doesn't look too bad either...probably is more bug-free than WordPerfect, but I haven't used either one yet... Anyone have any comparisons?

>
>Shareware, hah!
Well, let me put it this way. The way you worded the message was pretty
poor, in my opinion; that would immediately cause me to (a) hack the
message out of the program myself or (b) simply file the programme in
the Circular File. Further, if this was over about a year ago, the best
terminal emulators on the PC were PD or Shareware anyway- PCTalk comes
to mind, though they've since gone commercial. But for you to bitch
because the shareware system didn't work for you is pretty infantile.
If the programme is good and professionally done, people DO support
it (at least in the PC and Amiga world; it doesn't work on Commodore
8-bit machines and I can't speak for the other markets), assuming
you promote/distribute it properly! Shareware to me is infinitely better
than the commercial market because (1) the programme must sell itself
and (2) only the good programmers make any money.

Just for the record, I *have* released Shareware, and I have made money
off it. Not much, because the programme was a C64 thing, and it was
mediocre to begin with, but a good bit for a week and a half of programming.

This sounds suspiciously like the Electronic Printing Systems
division of Xerox Corp., and their tabletop 4045 laser printer,
resolution 300 dpi, similar control language to their 2700 printer.
If it's the same beast, you had best be prepared for incredible
headaches in trying to use it with your ST's. If you already are
an expert in the 4045's internal formats (especially of fonts), you
may have a chance of using it, but it has peculiarities that can make
it frustrating and unpleasant to deal with.

From: apratt@atari.UUCP
Message-ID: <973@atari.UUCP>
Source record: 254659

Here's the story:

GEMDOS has a statically-allocated memory pool called the OSPOOL. It is of fixed size. Directory descriptors are allocated from this pool. So are file descriptors, handles, and other things.

The memory allocation for this pool is pretty bad. Mainly, once a directory descriptor is allocated from it, it only gets freed when there's a media-change on that drive.

Hard drives never show media change, so directory descriptors are never freed.

When this pool is exhausted, bad things happen. Most of the OS checks for failure to allocate, but parts of it don't. When you have exhausted the pool, you will get empty directories where you expected files, and other odd behavior. You can even lose the data on your hard disk because writes are made on the basis of invalid data structures, but this is pretty rare.

The upshot is that you can't have more than about 40 folders on all your hard disk partitions combined. Hence, "the 40-folder limit."

The program FOLDR100.PRG adds 100 folders to the limit. Place it in your AUTO folder. (That is, a folder called "AUTO" in the root of the boot device.) If you rename it to FOLDR050.PRG, it will add 50 folders to the limit, and use up half as much memory. Note that it looks for the file "<boot device>:\AUTO\FOLDR???.PRG" for the number of folders it should add: that's the only file name which matters.

The next release of GEMDOS has this bug fixed. The limit is pushed so far away that nobody will run up against it, and if they do, FOLDR100.PRG still works. (The remaining limits are on things like the maximum DEPTH of a folder, and on the distribution of open files.)

That's not the only improvement I have made to GEMDOS. Other notable ones are much faster FAT handling code (so much-used hard disks don't run much more slowly than empty ones) and other miscellaneous fixes.

The completion/beta test/delivery schedule of the release that will include this improved GEMDOS is currently being discussed.

> I have a question about the GEMDOS Mediach() function. My MWC manual says
> this function can return a 0, 1, or 2, meaning "no", "maybe", or "yes."
> What situation would cause Mediach() to return "maybe"?

When you have a situation where the BIOS can't detect (for sure) if
the media has been changed or not. For instance, if you have a
write-protected disk in the drive, and the drive has been idle for
over a second or so, the state changes to "Maybe".

You can still yank out a non-write-protected disk and put it back in
the drive. So the "Maybe" state really reflects the fact that the
BIOS hasn't had a chance to match disk serial numbers yet.

> file structure. Hmmm. So we considered changing GEM...

Actually, CDOS was DRI's "black hole" project. It kept eating manpower,
and a lotta people wanted off. This is relevant to:

> But then a systems programmer said that _he_ could write a new operating
> system in a month that would look just like MS-DOS from a functional
> standpoint, and would be great and perfect and peachy-keen. And he did -
> pretty much alone. And since Atari was in such a hurry, they took what we
> had before all the horrid problems in it cropped up.

The mists of history part...

GEMDOS was originally written by Jason "Born to Code" Loveman, a
programmer on DRI's CDOS effort. So sick of working on file systems
during the day, he went home at night to spend time writing his own
file system on his Compac. HE did it HIS way.

CP/M-68K was "okay", but that didn't mean stellar. That means we were
looking for just about any alternative (real folders sure sounded
better than 16 user areas, though we didn't know about the 40-folder
limit at the time).

So we did a port of GEMDOS for January 1984 CES; it was in ROM at the
show, though it wasn't pretty, and it was part of the reason we didn't
let anyone touch the very first six working STs. Over the next few
months GEMDOS gradually got more solid. We made a disk release of the
system in June of 1984, though we weren't too happy about it.

The next five months before the first ROM release saw little
improvement in the file system. DRI had fired Jason, and some new
people at DRI were struggling valiantly with his idiosyncratic
brain-child. We saw few updates from DRI, though we squashed quite
a few bugs on our own.

My favorite line to describe the state of GEMDOS (and TOS in general)
is still Han Solo's from The Empire Strikes Back:

"Whew! And I thought they smelled bad ... on the outside!"

> And later we fixed all those problems and then forgot about it. I don't think
> there's anyone here still working on GEMDOS.

DRI did not fix "all those problems." No one has (unless it's Allan Pratt).
It is very clear (though not very interesting, now) that DRI has abandonded

GEMDOS. Probably just as well...

Let me add my vote for RTX, if you'll publish the manuals for it. I would be very interested in calling RTX inside some of my programs; some of them cannot be completed without it. My brother has and uses the MT-C shell, but the system did not include calling conventions for RTX. I would be willing to PAY for the programmer's info (hopefully NOT pay dearly, though) if I could freely distribute RTX with the software.

I can't agree more with the concept of shareware. I think that it is
great that programmers release their efforts to the honor system,
caring more about producing worthwhile software than how much they
are going to make on it.

As far as the honest europeans goes though I beg to differ. It seems that
much of the pirated software that I have seen (not my own, of course!) has
been cracked in europe. And where do think the Swiss Cracking Association
is from. I just read this morning in a recent copy of AC that the new
revision to PageSetter was pass-word protected because european dealers
would not sell it without protection because of the problem with piracy
in europe. Of course we are not quite perfect here either yet :-).

Hello,

After reading the Article in Winter 1987 issue of START about
hooking up a second hard disk onto the SH204 disk I found an
add in Computer Shoper for a SyQuest SQ 306R removable 5 Meg.
system for only 179.00, "extra disks cost 35.00".

After hooking it up and using the Supra routines from GENIE I
am happy to report everything works GREAT. The only problem
that I have is that the ST does not know when I change disks.
The only way it notices a "new" disk, is when I reboot the
machine. Is there a program out there that will cause the
ST to re read the directory structure of a hard disk?

p.s. Hello Allan Pratt,

While you are fixing GEM could you make it so that GEM will
re read the Disk Structure from the disk (or what ever needs to be done)
when you hit the Esc key, even if it thinks the media has not changed?

Thanks alot,

....

Alice the Personal Pascal is totally different from OSS Personal Pascal.
It just happens to be a similar name. Recently Optimized Systems Software,
Inc. is brought by ICD. According to a press release from ICD, all the
existent OSS software, including Personal Pascal, will be distributed by
ICD. For your information, here are OSS and ICD addresses:

The solution is simple - homebrew your ST software to use GEM, and
have X-rocks buy GEM (and the dev kit) for your MS-DOS system!

Excuse me if I'm mistaken - but why not release the bug fixes now? As well
put it in the public domain. Since it is only useful to people with Ataris
and major bug fixing like this should have been done from the start, I see
no reason not to let people burn their own roms to fix the operating system.
If its left to Atari, we won't see this for at least 1 year!! I'm not even
asking for the source - just a romable executable file that can be distributed
on usenet/bitnet/atarinet etc.
Is support like this too much to ask, or does Atari see $$$ in new
rom sales and/or developer registrations for this?
/Leonard

>PLEASE!!! Spare me!!! The word, despite the official mis-spelling of
>the CBM Corp., is "kern-E-l".

Its only the official mispelling on those machines that have that particular
jump table that acted as the basis for the OS...(the Amiga has a graphics
kernel, for instance) But what disappointment! Here I was, waiting for
a multitasking C-64 OS, and you cruely dash my hopes :-(

There's an interesting (well, sort of) story behind the kernal and how
it got to be spelled that way , which you can hear from many of my
old friends at Atari :-)

>>parameters in the HD are trashed after running the Atari utilities.
>>Here are correct values of the trashed parameters in logical sector 0
>>of each HD partition: (the trashy ones sure looked suspicious!)

OK, here it is again, with the offsets into the boot sectors (which are
logical sector 0 of each partition, NOT the first sector of the physical
disk, which holds the partition info and autobooting code). (Mr. Pratt
at Atari told me that the BIOS function Rwabs() with r/w parameter of 0
reads the logical sectors of the partitions, but with r/w = 2 and record
number = 0 one can read the master boot sector.)

offset bytes correct trash

10 1 NFATS 02 20
15 1 MEDIA F8 73
18 2 SPT 0011 2E70
1A 2 NSIDES 0004 2C73
1C 2 NHID 0001 2076

(all in hex). Note that the 2-byte entries are in INTEL format,
i.e. low-order byte first! (That's for MD-DOS compatibility.)
I also put F8 in the first sector of each copy of the FAT
in each partition, just in case (the fix program from A.G. does not do that).
They say you must fix it again after EACH TIME you run HDX or HINSTALL.

>... However, PCDITTO
>fails to recognise that I have any hard disk at all, whatever I try.

You need PCD version 3.0.

- Moshe Braner

I have gotten Compress to compile, and I have pulled out decompress as a stand alone - if what you are talking about is the 16 bit LZ compression program that produces .x and .zx files. The original source is available in one of the groups and compiles (under 2.1.7 MWC) - you just have to pick out the MSDOS ifdefs for only the files and go normal for the rest.

I don't think anyone could speak for any two specific pieces of hardware, but what may have happened is that the first file wasn't closed for some reason, so that the directory structure was damaged, then when moved the other OS did it's best to fix it. I am using PC-Ditto which abandons TOS entirely and can even make it understand twister disks. I am assuming dos 3.2 or greater - and using IBM/MSDOS drivers. Some drivers may only support 9 sectors or assume them on a 10 sector disk, which the ST might intermingle. (intermangle?:-). By the way, I am using a utility that adds the stuff that MS Dos wants to my ST formatted disks, and am not using PC-Ditto's custom drivers.

Regarding the comments on "shrink-wrap" license agreements.

The previous posters are correct in stating that such agreements have never been tested in court. There are several good reasons why I believe any such case that gets into court will have shrink-wrap thrown out on its ear.

*** Disclaimer ***

I am not a lawyer. This is not legal advice, only my conjecture on what might happen to a hypothetical case concerning shrink-wrap.

1) When you go to a store and buy software, you essentially complete a sales contract between the vendor and yourself. In the case of a store, generally the vendor is not the party who has an interest in the license agreement, meaning that the software publisher (or whoever holds the license rights) is attempting to be a third party in this contract. Unless the vendor specifically calls attention to the license agreement before the sale, it is possible that the intended buyer did not read the license agreement on the back. There are many reasons why this could be so, i.e. the software could be in a display case or you may have bought by mail order.) Unless provably stated otherwise at the point of sale, the contract is between you and the storekeeper.

The only vendor I know of who has this covered correctly is APDA. When you "Join" APDA (really you submit to the licensing arrangement), you sign a statement that you will read the back of any software you buy and return it if you do not agree with the wording. This may not be enough to satisfy the courts, but it's better than most.

2) In the case of the "Break this seal and lose all your rights" type of business, this seems to be the weakest type of licensing. When no agreement is visible from the outside of the packaging, any internal notice would be trying to enforce a condition of the sale after the sale has taken place. In order to create a valid contract, (like a sales contract), all terms of the contract must be known to all parties before the contract is consummated. You can't throw in another condition after the sale has taken place. Suppose the seal said: "Break this seal and you owe us another ten dollars." or "Break this seal and you must vote Republican at the next election." It's like buying a loaf of bread and when you get home, find a band wrapped around it saying "By breaking this seal, you agree not to give any slices of this bread to Owen Hartnett."

Any real lawyers care to comment?

From: jpdres13@usl-pc.UUCP
Message-ID: <827@usl-pc.UUCP>
Source record: 254687

In response to my own earlier plea for help, I have found that the reason for the keyboard & mouse lock up was, sure enough, loose chips.

I opened the 1040, went under the drive & pushed down on all the chips. One of the two 24 pin chips next to the sound chip was not seated all the way down. I looked up the chip in an "Internals (Abacus)" book and sure enough, it was the chip for the keyboard, mouse, & timer.

Better yet, I am once again breathing normally, pulse rate near normal, brew in hand, and everything is working normally.

I wonder if this has anything to do with the snow that hit the deep South of Louisiana last night for the first time since 1973? Maybe the change in barometric pressure popped that chip up just a tad... And if I would have had a computer in 1973 (Altair dreams?), it would have popped up a chip also?

Part of the reason for the failure of most Shareware products to realize the author any remuneration for his time and effort is simple ignorance of a basic showbiz tenet: always leave 'em wanting more. Relying upon the expansiveness and generosity of the public to compensate the author for what they already have looks good in pious policy statements but the facts speak otherwise. Very few people contribute unless you give them an additional reason to. This might be a bound manual or source code or something that the purist element might resent: limited program features. Or it might include technical assistance (for a program that might demand it).

I think that any potential Shareware author should plan his distribution with at least SOME observation of basic marketing psychology. If you give away both the carrot and the stick then your "sales pitch" is going to be no more effective than standing on a corner with a paper cup.

1639. Free Multitasking Kernel?

Newsgroup: comp.sys.atari.st
Date: 1988-02-07 11:49:20 UTC
From: HAHN_K@DMRHRZ11.BITNET
Message-ID: <8802071149.AA05843@ucbvax.Berkeley.EDU>
Source record: 254689

Regarding the 'multitasking-war' that just calmed down I think it's time to put the whole thing on the feet again. David Beckemeyer asks about our opinions concerning a PD-RTX and the problem with the loss of profits out of the product. I say: don't give it away for free. Take a closer look: people who *really* have to use a multitasking kernel (like me) can easily afford a few bucks (look at the ads to see that it's really a bargain) because they are usually making money out of it. And people who are *really* interested in such systems and want to know how to use them could spent the money as easily. So it's not a problem of money at all.

But that's not the main point. What do those people working with multitasking, communicating, interrupt-driven processes need most? Obviously they need support. Just around these days I had some problems with RTX and asked David. Although the docs say that he doesn't have the time to give such a moderatly priced product extensive support, he answered instantly and gave all the re-
quested information.
I herewith vote for a well behaved, carefully documented, regularely updated, adequately supported and decently priced product.

>now it was Alice The Personal Pascal !

Really doubt this, since I have heard from 3 sources that ICD is in the progress of buying OSS. And one source says that it has already happened. I really hope this is true, since that should improve the integrity of OSS Pascal a lot (unless ICD concentrates more on the 8 bit OSS products first, since that is where the money probably still is.)

>As I do not believe what he told me, could anybody give me the full address
>of OSS (with e-mail if any, or telex) in order for me to ask them if
>they have a European distributor (idem for the Tackle Box).

May as well wait a few weeks to see how things settle out (or check around and see if your distributors carry ICD products already for the 8 bit line of Ataris).

>protecting his SHAREWARE product, which allows a user to sample the
>product, yet requires an end-user to pay IF and only IF he/she intends
>to use it regularly.

I disagree. The author has released a product that is virtually
unusable. I would use it once or twice, get disgusted, and toss it
out on general principle. So would most of the people I work with,
and most of my friends.

The fact is, shareware licenses are unenforceable. People know
they're not going to get caught, so legal threats don't bother them.
They aren't made to feel guilty by whining pleas for money.
Shareware is a noble but stupid idea. It's based on a flawed view of
users. It's almost never worked, and I'm pretty certain that it
never will.

If I had a product that I wanted to sell, I'd try to market it
through one of the major vendors, or I'd buy 2x3" ad in Amazing
Computing or Amigaworld and take my chances. Perhaps I'd distribute
limited capability demo copies for free. I think that would be a
great way to distribute a game (assuming it's something playable). I
would *NOT* distribute via shareware. Statistically, is a stupid
way to try to make money.

If I wanted people to have the program for free, I'd copyright it and
provide for free redistribution. No point in pretending that users are
something they are not, and no point in looking forward to money that
I'm not going to get.

1643. Microsoft Word for the ST

Newsgroup: comp.sys.atari.st
Date: 1988-02-07 20:43:44 UTC
From: rowley@ORVILLE.NAS.NASA.GOV
Message-ID: <8802072043.AA15363@orville.nas.nasa.gov>
Source record: 254693

I saw Microsoft Word for sale yesterday at HT Electronics in Sunnyvale.

The advantages of the program are that it seems to be a decent word-processor, it can use multiple fonts, and it produces output with GEM metafiles. However it does not include a spelling checker.

The package comes with GDOS, and a device driver and fonts for the Atari dot matrix printer. Included is a set-up program for GDOS. It appeared that Epson-compatible and 24 pin printers are not supported for output of GEM metafiles in this package. They were using device drivers and fonts from Easydraw on an FX-80 compatible in the store, and the output looked good.

The GDOS document and utility programs look good. Atari should consider selling the GDOS programs and documents separately from the Microsoft Word package.

At the store they had a copy of a utility program that could convert Mac and Amiga fonts to GDOS fonts.

.
This is a simple question. Does Magic Sac have MIDI support? If it does,
I and many of my colleages will buy it.

1645. Re: RTX, MT-C shell, TOS compatibility?

> [much removed]
>So, will MTC-shell and/or Micro-RTX do the following?
>
>Run existing non-GEM programs, like MicroEmacs?
> In the background?
RTX will indeed run non-GEM programs in the background. This includes commands like compilers, makes, arc, kermit, and most other *.TTP or *.TOS programs. Interactive programs like MicroEMACS are not very useful in the background however. But they can be used from an auxiliary terminal, while something else is going on the the ST console.

>Run exisitng GEM programs, like Uniterm?
> With others in the background?
> Switch between GEM programs?
> Switch between non-GEM and GEM programs?

RTX will run existing GEM programs. These must be run from the main console screen (of course). Only one GEM program may used at a time; RTX does not re-implement the GEM calls, only the BIOS and GEMDOS calls. Non-GEM programs may be running concurrently with the one GEM program. There is also a way to switch between non-GEM programs and the GEM program, via a Desk Accessory (which is also a way to "simulate" multiple GEM programs).

>What limitations are there? Thankx.
> fred

The main limitiations are memory and "ill-behaved" programs. RTX is a "in memory" system (i.e. it doesn't swap). Also the ST has no hardware memory management, and only the "low memory" protection. When RTX runs out of physical memory, no more processes can be started until one finishes. As for "ill-behaved" programs, we're mostly talking about programs that forsake the OS calls for "speed" or some other reason. If the application makes TOS calls, it will usually run. If it hacks hardware directly or otherwise bypasses the OS, then most likely will not run.

>upgrade (only 32K, not 200K like RAM TOS was).

As for me: a RAM-TOS boted from hard disk would do. But since AHDI will not work with RAM-TOS (why?)...

I just spent 68.00 Deutsche Mark for a C-Source of Gemdos published here in Germany and like some other people I will try to compile my own TOS, if possible at all.

I would like to hear rumors about Atari talking to David Beckemeyer about RTX becoming the new Rom set; I dont think it is possible to make GEM support multitasking, but TOS sure could get more useful.

In article <22558@brunix.UUCP> rjd@nancy.UUCP (Rob Demillo) writes:
>people here at the lab recently (Dec) bought a 1040ST thru Lyco.
>He payed a great price (around 650 for mono). Now in January another
>fellow in the lab decides to get a 1040 from Lyco. Current cost: $850
>What happened?

Nothing more than Atari raising dealer prices across the board from what I hear from other dealers locally. I only know of the single $100 increase on the 1040, but the girl at CMO mentioned that they have seen two price increases in the last few months on the 1040.

Same thing happened here at ETA...one guy bought his in mid December for $150 less than another got his for in mid January (think the last price was $940 for an RGB 1040. Still another person just bought his at a local store for $1050 or so. From what I hear, both the mail order people are happy with their machines and the other guy probably will be if the store ever gets their shipment in...but that's another problem altogether.

1648. Redirection of program output to my own routines.

Newsgroup: comp.sys.atari.st
Date: 1988-02-08 01:58:51 UTC
From: wayrynd@jacobs.cs.orst.edu
Message-ID: <2458@orstcs.CS.ORST.EDU>
Source record: 254696

There have been several questions asked on how to force program output
to a different device. My question is simular, in that I want to direct
a programs output, but not to a device, but to my own display routines.

I have wrote a 130k baud non scrolling, adn 31K baud scrolling screen IO
package simular to Tempus and the PD program ASL. I am writing a bbs, and
want to run external games, but want to use my own screen IO routines. Not
only because they are faster, but becasue I allow user definable fonts (ala
Degas 8bit fonts).

I know it is possible to redirect the output to a routine of my own, as
several Gem based shells for compilers can redirect standard IO to their own
window. (Laser C will redirect stdio).

If anyone knows how to accomplish this, or is interested in the screen IO
package let me know at one of the following places, or by replying to this
message.

1651. About shareware....

Newsgroup: comp.sys.atari.st
Date: 1988-02-08 07:02:55 UTC
From: ihnp4!pell!orc@stag.UUCP
Message-ID: <330@stag.UUCP>
Source record: 254699

I've got a couple of programs out there as shareware (Levee and the teeny-shell) which have gotten almost nothing back to me ($5 -- once -- for Levee) and I've got STadel, which has, up to now, pulled in almost $800 for me. STadel is as free as the air, but I will support it (my bosses say that I support it better than I do the stuff they pay* me to do....) and fix all the (multitudes of!) bugs that pop up in it. Possibly I get $$$ for it because it's so much better than ANY* other BBS program (Inner Sanctum -- the STadel mutant -- included) that's out there for the Atari ST.....

Hell, STadel paid for Pell. Which is all that matters (Pell destroyed my 520, so I had to get a 1040. Why* I did this I don't know....)

From: ihnp4!pell!orc@stag.UUCP
Message-ID: <331@stag.UUCP>
Source record: 254700

In an article a day ago (sorry, STadel doesn't give me message ID's --
thank god!), wes@obie.UUCP said something about using Fforce() to redirect
i/o. Well, his example was wrong. Fforce is passed two file descriptors and
it forces the first one to point at the second one, like so:

```
/*
* redirect printer output into a file
*/

foo = Fcreate("a:\printer.out", 0);
save= Fdup(PRN); /* wanna save the old printer... */
if (Fforce(PRN,foo) == 0) {
/*
* do printer stuff
*/
Fclose(PRN);
Fforce(PRN,save);
Fclose(save);
Fclose(foo);
}
else
Cconws("ACK! Can't redirect the printer!\r\n");
```

(I hate so see this already brain-dead OS subjected to further indignities :-)

1653. st->rf and st->misc.add-ons

Newsgroup: comp.sys.atari.st
Date: 1988-02-08 09:12:16 UTC
From: c60b-at@buddy.Berkeley.EDU
Message-ID: <616@pasteur.Berkeley.Edu>
Source record: 254551

From the news I've caught up on, there seems to be a st to rf/composite converter. Could someone mail the address(es) of the company(ies) that make this type of device.

Also, is there any info on converting a 520/1040 so the 68000 bus is open, like on the megas. It would make it much easier to add memory and the blitter (and other goodies).

To Atari:
How about yet _another_ OS for theST. If Beckemeyer's RTX is solid, I say supplement gem with it. We NEED a good inexpensive OS. As it is, the choice is between paying $$$$ for a workable multitasking system or getting by with a crippled os.
Atari, wake up and realize that under the current OS, the ST is about as amazing as a PClone running at 10mhz. already, they have fake multitasking at a good price (for them a good price). Unless there is a clear advantage to getting an ST instead of the "Industry standard" why get an ST? If I'm going to pay $1500 for a Mega 2, I expect more than something that barely does better than a similarly price PClone.

The best program to accomplish this is called barrel written by
Moshe Braner. It has several functions to allow capturing text or
screen dumps to a file. It is TSR (terminate & stay resident) which
may or may not be what you originaly wanted, but it is good and it
works....

In article <15@obie.UUCP> wes@obie.UUCP (Barnacle Wes) writes:
>You can redirect the output to printer in your program via the
>following:
>
[part of sample deleted]
> /* Now execute the program, the standard handles are inherited. */
> Pexec(0, "disk:/program/name/path.prg", NULL, tail);
>....
>
> Hope this helps whoever it was!

Not likely... The example you gave will bomb miserably... The
parameters you gave for Pexec are in the wrong order and ignore an
important pecularity in the Pexec call (the command tail is a Pascal
style string, not a C style string).

The correct order for Pexec parameters is:
Pexec mode: zero is fine
Program name: standard C string format
Command tail: a pointer to a Pascal style string (a string
with the character count in the first byte!)
Environment: A pointer to an environment block or NULL if
you want to use the default environment.

Thus, a corrected version would read:

static unsigned char tailbuf[255];
....
tailbuf[0] = strlen(tail);
strcpy(tailbuf+1,tail);
Pexec(0, "A:\\folder1\\folder2\\program.ttp", tailbuf, (char*)NULL);
```

>really going on? thanx.
> fred

Sounds to me like you got a disk error. Ever hear of one of those?
Wierd things happen even when you work on one machine, it doesn't have
to mean that machine's incompatable (in some misterious way) with
itself.... It could also mean that one of the drives, the one on your
ST or the one on your PC (or -both-) are out of allignment, need
cleaning, or are in the midst of head failure. Could also be the
disk. Even though I regularly buy single sided Sony 3.5" disks and
format them double sided with no problem, of maybe 5 disks that have
failed (out of ~400) two of them were double sided. It happens...

In short, try it again... Maybe with a different ST drive. Maybe
after you have your PC and ST drives both checked out by a good shop.

It can be done...

I've heard this one before! It's in the same category as "nobody will ever
need more than 65K of memory" and "no one will ever need C structures larger
than 32K". I would prefer to hear that the file system limits depend only on
the amount of physical memory available - people at Atari are not so clever as
to know what programmers are going to need! It's this kind of hubris that
makes me wish for licensing of software engineers...

1659. Icon 6.5 on ST's.

Newsgroup: comp.sys.atari.st
Date: 1988-02-08 16:16:06 UTC
From: NETWORK@FRSAC11.BITNET
Message-ID: <8802081518.AA27950@ucbvax.Berkeley.EDU>
Source record: 254557

Good (?) news for Icon language fans on the Atari ST:
Icon 6.5 for Atari ST is available from 2 network servers:

For Arpa and related networks: you cant FTP it from
megaron.arizona.edu , in arc'ed format.

For Netnorth/Bitnet/Earn: just ask for the files
in the CANADA01 Listserv. (arc'ed and uue'ed)
Files are PROG-A16 88-00042 to ...45
(Example, from a VM site:
tell listserv at canada01 send prog-a16 88-00042
....
tell listserv at canada01 send prog-a16 88-00045
to have the list of all available files:
tell listserv at canada01 index prog-a16)
I am trying to collect some documentations and examples to be
posted at this server.

Can somebody make this available for anonymous UUCP ?
It is too large for general distribution.

I may send a few, in Europe only, for non-arpa/non-earn nodes only.
(If you can convince me your network address is good, and nobody
around you already got it.)

Have fun.

From: oscar@devvax.JPL.NASA.GOV
Message-ID: <1246@devvax.JPL.NASA.GOV>
Source record: 254558

I was looking for a hard for my 1040 when I came across this company in Webster, Texas, MEGABYTE. They had what I considered to be very good prices on harddisks and also seemed to know what they were doing when I talked to them over the phone. ..BUT.. it is another case of it is being shipped today, followed by we will be getting a part tomorrow, followed by yours is at the top of the list.

I can understand this on software where schedules are sometimes not able to be kept but hardware is a matter of counting the number of oredrs and counting the number of parts and asking ones self do I have of enough.

I am about ready to cancel my order because I wonder if a company can't tell if something is in stock or not how good would they be at fixing it?

Has anyone ever delt with this place before?
If so what is your reaction?
Any suggestions where one might get a deal on a hard disk for the ST?
(I sould prefer a 30+ if at all possible?)

Thanks for any response

The board from Datafree ha to be soldered in (only 17 points on a
template). This was done on purpose - If you spend $$$ on 4 megs
of memory you don't want to have to reseat a loose plug-in connector
every 6 months - believe me it happens. The first version of Datafree's
board was a solderless plug-in board and no matter how a connector was
designed, it would eventually come loose - maybe thats why no major
manufacturer of sockets even makes a header for quad-pack sockets.

In article <8802051030 31DE1.AVLQ@Mars.UCC.UMass.EDU>, Flash@UMass.BITNET (Rick Flashman) writes:

> Anyone know what is the deal with Data Pacific.

I purchased one of the first lot of MAGIC SAC PROFESSIONALS. Shipment was promised in November, arrived a month late, in time for Christmas ... one expects this with a new product, I had no problem since pre-XMAS is a time pre-occupied with lots of other things anyway. The Translator-1 arrived, worked fine, a few "undocumented features" (which one expects with a new product). The software support for Data Pacific continues to set the kind of example that I wish the other software/hardware suppliers would follow: one free update of the software included with the original purchase. Version 5.9 of the MagicSac software arrived in the mail a month after Version 5.5, along with a chatty Newsletter, with hints like: good karma is System 3.2 Finder 5.4, and bad karma is long file names (> 21 or so) with the Hierarchical File System (HFS). Version 5.9 fixed problems with the ICD hard disk interface, so now Magic Sac works with ICD as well as the other hard disk interfaces (Atari, Supra, BMS, etc).

The MagicSac lets me run software which is never going to be ported to the ST. I'm definitely a satisfied customer.

> kind of fishy after the 6th time.

Data Pacific had some terribly bad luck with their first batch of Translator-1 assemblies. They contracted to an assembly house which inadvertently substituted a chip with a very similar part # ... the substitute fried the CPU when power was turned on. This set the folks at Data Pavordnysk behind about a month ... I've de-soldered chips on my ST ... it takes time to desolder, resolder, test, burn-in, etc ... lots of time.

I imagine they've been very cautious with subsequent lots ... burn-in, tests, etc. Demand has been high ... The MAGIC SAC PROFESSIONAL is all that there is if what you want is a Mac clone.

Since demand appears to have outstripped supply, delays can be expected.

> Talked to David Small on GENIE who promised to look into it, since he is
> also claiming that they are shipping. Never got a reply.

You can send email to David Small at dsmall@well

There's a mailing list for MagicSac users ... to get on the list, send email

To: mcli@ur-tut.UUCP (Maurice Ling)

Subject: Magic Sac Newsletter update

> Annoying part is, that this stuff was/is for a goverment BID. You know how
> those are picky on product delivery.

It's fortunate there's a 32K limit on news items. This could start
a variation on the "Multi-tasking: A Nightmare" blizzard.

I assume you're proposing hard disk systems.

Be aware that MagicSac presently does not support the 128K ROM.
Though 80% or 90% of the current Mac software can be used, that
percentage can be expected to drop as more and more products become
dependent on features in the 128K ROM. No HyperCard, and no HyperCard
based software. No System 4.0 or beyond. This is OK for home
computer enthusiasts, who make cost effective decisions: purchase 80%
of a Mac for a fraction of the price.

From: pauls@inco.UUCP
Message-ID: <1325@inco.UUCP>
Source record: 254565

A few months ago I noticed a news item announcing that Diverse Data, Inc was working on a product called a MEGACASE ST (and a MEGACASE ST DELUXE) which supposedly let you put your 520ST (or 1040ST) motherboard in a box that looked like a MEGA-ST, with a detachable keyboard, and maybe some half-height slots and a power supply for hard-disk drive, floppy drive, etc. Makes it easier to upgrade memory, etc.

Does anyone know anything about this product? The news item did't include the address or phone for Diverse Data. Are there any other products like this? I'm planning one of those do-it-yourself hard disk drives, do-it-yourself 5 1/4 floppy, etc. and like many 520 ST owners, would love to thrash that pile of power supplies. Please email. I'll summarize if there's enuf interest.

Thanx in advance.

I have no problems with running UniTerm under MT C-shell (it does halt other running progs), MicroEmacs will allow other programs to continue running in the background unless what you're editing is really big. Gulam works as a shell under micro-rtx in place of csh (so does msh), and I run compilations using MWC in the background all the time. Tell me, please: Where does your info come from? I have had no problem running MWC, I'd finally throw this machine away if I had. I haven't had to recompile ANY of the MWC utils to get them to run, either! One thing that doesn't seem to work: UniTerm can't open files when using Kermit for file transfers under MT C-shell. Works okay for xmodem or ymodem or ascii, but it doesn't like something that kermit is doing. Protections, maybe?

From: alexande@drivax.UUCP
Message-ID: <3046@drivax.UUCP>
Source record: 254570

Landon Dyer's summary is accurate in the broad sense, although some of the unimportant details weren't quite right.

I think it's a mistake to blame just one individual for the problems with GEMDOS. For sure, having programmers that aren't motivated to produce good work doesn't help. But that project also suffered from extremely tight, over-optimistic schedules that couldn't be met without compromising quality.

Maybe DRI marketing types thought the Atari deal would bring them the glory and bucks they lost when Microsoft got in good with IBM. Frankly, it didn't work. After reality set in, it was apparent that DRI would never make much money off the Atari. That's probably why they never put much effort into really fixing GEMDOS.

Disclaimer: I don't speak for DRI. These are my own opinions and observations.

As one of the last people to work on this project (with one exception), I can only add my support to most of the comments from Atari and DRI sources, particularly Landon's quote from Star Wars. If Atari has only fixed a few bugs in that system, then they are to be commended from it. As Mr. Pratt probably knows all too well, it is far to easy to swap new bugs for old ones without re-writting major chunks.

Mark sums up the "motivation" behind the results: mostly marketing types working out deals with unrealistic schedules behind them.

Bruce's comments on the origin, while simplistic, are not too far off base. If generalized, they apply to much of the system that someone else (sorry, forgot the name) was complaining about (eg, Alcyon came, er, for next to nothing, and was "already complete").

As most programmers know, if you do a bad (read: hurried) job the first time, it will most likely take longer and longer to get seemingly small bugs fixed.

My sympathies go out to Mr. Pratt.

> that will make your box more than an expensive paper weight. You HAVE
> priced the software your going to need?

An admiral Idea except for one little thing, WHAT IF I RUN OUT
OF MEMORY. Well the ST is not a vertual machine. That means you have
to have available whatever memory you are going to use. One might just
think that 512K for a single user machine is a GODs plenty. Well its not.

I have a deskcart plugged into the cartridge port and do a lot
of work with Mark Williams C running with Beckmeyers Multi-Tasking C
Shell. Several times I have run up against the wall of not enough memory
with my 1040 ST. Then I have to get rid of the ram disk and set so my temp
space is somewhere on the hard drive. This slows down compiles quite a bit.

My point is if you ever expect to expand the machine to really do
anything other than be an expensive "lets-look-at-the-graphics" toy,
you might as well plan for the future and puchase the 1040 now. If you plan
to use it for the kids and a toy, fine the 520 is dandy.

'Megamatic' from TGIF Software works fine with Megas. It also includes a print spooler (you can empty the buffer with ctrl/alt/0), a screen saver, and reboot-keys (ctrl/alt/. for 'warm' boot, ctrl/alt/* for 'cold' boot). The RAM disk and spooler are sizeable, and it comes with a reasonable doc. I think it's shareware, I found it on BIX.

1678. UUPC: How to disable the automatic archiving of outbound mail

Newsgroup: comp.sys.atari.st
Date: 1988-02-09 07:47:56 UTC
From: skl@van-bc.UUCP
Message-ID: <1669@van-bc.UUCP>
Source record: 254577
Cross-posted to: comp.mail.uucp,comp.sys.ibm.pc,comp.sys.mac,comp.sys.amiga,comp.sys.atari.st

Question: The mail command in UUPC automatically files all outgoing mail I sent into a mailbox file (the name of this file varies depending on which micro you are on), how do I disable this so that none of my outbound messages are ever archived?

Answer: Replace the content of that archive file with the text "Forward to {BitBucket}" and the copy of the outbound mail that is supposed to be archived will now get re-routed to the bit-bucket. Note that cases *is* sensitive here and there must be *nothing*, not even a '\n', after the string.

What you put in place of the "{BitBucket}" string above depends on which micro you are using. On an IBM-PC/MS-DOS system, the name of the infinite-waste-basket-device is "NUL". On an UNIX system, it would be "/dev/null".

The name and location of your outbound mail archive file also varies depending on the type of micro you use. On IBM-PC/MS-DOS and the Atari-ST, the pathname of that file is "$HOME\Mail\mailsent", where $HOME is the name of your home directory, specified in the environment variable HOME. On the Macintosh and the Amiga, this pathname is "$HOME/Mail/mail.sent".

T. Bailey asked:
>If anyone knows,
.....
> Is there an update to DBMan v.2.02, and is there an "assist" style
>GEM interface available? (Neil??)

In a letter, dated dec 11 1987, Versasoft (the writers of dBMAN) offered
me an upgrade to version 4.00. This version should read and write dBASE III+
files, knowse about BROWSE and memo-fields and should run most dBASE III+
applications without modifications. The ASSIST funktion was already there
(in version 3.X) but was in fact a sophisticated application written in
dBMAN itself. In dBASE III+ it's a function. (dBMAN: do assist, dBASE: assist).
It (v.4.00) should be faster too. Mouse driven menu's were already possible
in version 3.X.
I upgraded to version 4.00 but I didn't receive anything yet, so I can't tell
you if everything promised will work too.

Here are two stories belonging to software piracy. They may not be worth more than two cents, but here they go anyway.

>Shareware is a great concept except for one small detail. It relies on
>the honesty of the participants. In European countries, that wouldn't be
>so bad (at least from my experiences...I have lived in Europe for 13 years).

I do not comment on that although I'm a European. I think it would be better never to tell such things again. Why? See below!

Last week I made an interesting experience. I had contact to many software houses. And ALL OF THEM are piracing software from other companies. You see, they make a living out of selling software but the don't hesitate to use software from other manufacturers they didn't pay. I asked the management what they would do if someone just copied their software and would give it away to his friends so they could use it for free. I think you can imagine what they said. Then I asked them why they pirate software themselves. "Oh", they told me, "that's not the same thing. We had that customer who had that software, and you know, we needed it. And why should we buy it. We have it now, and it's definetly much more cheaper." (Ok, I can agree with the last point :-)).
As long as software houses steal software there is NO WAY the situation will ever be better. (Maybe US software houses are more honest in this aspect. I don't know, I never lived in the USA).

The other story:
(Many of you know it already, especially the readers of one peculiar newsgroup. I don't tell you in this article what kind of computer was involved. Don't ask me why! I just don't know.)
Some time ago someone developped a Virus which copied itself onto the next disk that you booted from (unless you turned power off, of course). After some time it just displayed a message. It was meant to be harmless - no hidden formatting or so. Ok, there was an unwished side effect but that's another story.
What happened to this virus. Well it got spread around the WORLD in about two months. And because it copied itself only onto the next boot floppy it was spread mainly by illegal redistribution of copy protected commercial software. (You had to boot from those floppies.) It was quite a shock for software companies to learn about how fast there products are copied.
But that's not the point I wanted to make. The real point is, that if you go to the software shop in your neighbourhood and buy a package which comes directly from the manufacturer, still wrink wrapped, you will find the virus on it.

Have a nice day, anyway,
...urs

<apratt@atari.UUCP (Allan Pratt)> writes...
> The memory allocation for this pool is pretty bad. Mainly, once a
> directory descriptor is allocated from it, it only gets freed when
> there's a media-change on that drive.
>
> Hard drives never show media change, so directory descriptors are never
> freed.

Would it be possible to fake a media change for a hard drive? If so, a small TSR could be written that would sit on the V-blank or 200Hz timer and cause media changes every once in a while. I imagine a media change on the hard disk wouldn't get in the way much, since it should be fairly quick to reload. Do you see any problems with this idea?

.....

And now, on a different topic...
<rogers@ncrcce.StPaul.NCR.COM> asks...
> Does dLibs or any other public domain library contain a version of "regexp"?

That's a good question. I have a partial version of "regexp", but I'm still putting the finishing touches on it. The Un*x standard implementation of this function set is really a kludge, but I assume that's how people will want them implemented. As far as I know, no other C library for the ST has these functions at all.

>of the above user. The author has found a very clever way of
>protecting his SHAREWARE product, which allows a user to sample the
>product, yet requires an end-user to pay IF and only IF he/she intends
>to use it regularly.

Again, this treads a fine line. I'm assuming (via the closed world
assumption) that the program was not disabled in any way. In that
case, what the author did is indeed clever; he discouraged theft. I
see no problem with calling this shareware - if people register like
they are supposed to, then the discouragment is removed. If they do
not, well, then they take what they get - a working program with an
annoyance that in NO WAY affects its functionality.

In a different light, authors that remove functionality (like
FontDisplay) until you pay, or authors who withhold documentation for
a complex system (Scholar's Aid) have no right whatsoever to call
their products ShareWare. They are forcing you to pay before you can
fully use their product. There is no difference between this and the
"Draw It Again, Sam" demo that was posted. At this point, they are
no longer getting "donations" for their work, they are soliciting
purchase. This makes them a commerical operation, but one which
offers no benefits of a real such organization.

I wonder what the people that have been using MIDI on the Mac for years
thought about this great new invention.
Seriously, have you noticed that most companies promote their new products
like they were the greatest/most important/most revolutionary invention
in the past two centuries?
Doesn't matter whether it's a new piece of computer equipment or a new
variety of hand soap, there's still plenty of hype. The computer business
is about the same as all the rest, no worse, no better.
The only difference I can see between the Mac world and the rest of the
computer business is a smaller percentage of blue suits.
By the way, I agree completely with the comment about increased costs. It's
one of the major reasons why MS-DOS clone makers can make their equipment
so cheaply, while major companies spend a fortune trying to compete with
each other's advertising.

>The only way it notices a "new" disk, is when I reboot the
>machine. Is there a program out there that will cause the
>ST to re read the directory structure of a hard disk?

Yes there is. A program written by Moshe Braner called UPROOT will
cause GEMDOS to see a media changed signal on any drive, hard disk or
floppy. I can send you a copy if you can't find it localy.

By the way... If you're using the Supra utilities, you should send
them some money. Last time I checked they were being nice-guys and
distributing updates via GEnie and Compuserve. Unfortunately, many
people have used Supras' being nice to SUPRA customers as though the
utilities were public domain (which they are not!). Supra has allways
been willing to sell their utilities to anyone, but only Supra
customers are suppost to receive the updates for free.....

If you don't own a Supra hard disk, send $24.95 to:

Supra Corp.
1133 Comercial Way
Albany, or 97321

to receive a disk with the utilities and documentation.

> net.
>
> Theodore Tang

My two cents about shareware: I originally distributed my Epson MX-80
to PostScript translator (in a very early form) as shareware. Total
amount received: $0. Do I know that anyone used it? Well, I got calls
from people asking when I was going to add graphics modes. I got a
question or two about it, and I found it was floating around various
bulletin boards.

So now, it's a commercial program, with nicely printed manuals, and
instead of asking $20, as I did when it was shareware, I sell it for
$50, and it brings in a bit of money.

Shareware will only work when people are willing to send in money.
I'm sure there are people who manage to make some money this way --
and I'm sure the people that send in contributions are about 1% of
the total regular users.

Well, I called MWC today (February 9), and was told

1) The next release would be 3.0
2) It is due out in 6-8 weeks
3) The C source level debugger will be available at that time
4) All registered owners will be notified in about 4 weeks

I spoke to Judy Petty, who is the official contact at MWC for the ST
compiler and support products.

1691. Re: Mega Compatible?

Newsgroup: comp.sys.atari.st
Date: 1988-02-09 18:54:10 UTC
From: dclemans@mntgfx.mentor.com
Message-ID: <1988Feb9.105413.7623@mntgfx.mentor.com>
Source record: 254591

The other hardware difference between the Mega and ST series relates to the clock. On the ST there is a clock in the keyboard cpu; on the Mega it's on the motherboard and removed from the keyboard. If a program is looking for a response from the keyboard clock I imagine it could potentially have problems.

1692. Re: How compatible are MS-DOS and TOS disks, REALLY?

Newsgroup: comp.sys.atari.st
Date: 1988-02-09 18:58:56 UTC
From: dclemans@mntgfx.mentor.com
Message-ID: <1988Feb9.105900.7658@mntgfx.mentor.com>
Source record: 254592

there are two areas to watch out for in moving floppies between
the ST and MS-DOS systems:

1. software
there are some slight incompatibilities between the systems
in boot-block and bpb handling; basically the ST sets the minimum
amount of information necessary, which doesn't match what some
MS-DOS drivers want

2. hardware
formatting/writing done on the ST with it's Western Digital
177x controller chip is not necessarily compatible with the
controller chips used on MS-DOS boxes; this is a case where it
might work, and again it might not

1693. New Printer

Newsgroup: comp.sys.atari.st
Date: 1988-02-09 19:23:30 UTC
From: keithr@vice.TEK.COM
Message-ID: <2269@vice.TEK.COM>
Source record: 254593

Has anybody seen or heard anything about the new HP DeskJet
Laser Quality printer? I just read an article on it in the
newspaper, but it didn't give enough specifics. It did
say that it was $995, 300 dots per inch, two pages per minute,
uses a replacable ink jet head ($18.95) thats good for
about 600 pages, it uses regular paper. The article also
said that it was HP and IBM compatible. OK, but what kind
of printer driver would I need? Is it Epson FX compatible
or what? Will I able to print output from EZ-Draw with the
standard driver and get laser quality? If anyone has any
more information on this new product please let me know.

Sorry to bother you all, but I really need to find some memory chips.
What I need are:
256K by 1 bit by 150 nanoseconds or
256K by 1 bit by 120 nanoseconds. I need 48 of them.

I would prefer chips by Mitsubishi, Hitachi, Fujitsu, or TI, but would
like to hear about any kind. Also, I would prefer the 150 ns chips.
120ns work fine in the board I have, but give no advantage.
I would appreciate any names/phone numbers/addresses of mail-order houses,
or direct from people who have such chips and want to sell them or anything
like that.

Please email me any information. If you can't handle ARPAnet, try
rlcarr%athena@eddie for UUCP.

If it bounces, post to comp.sys.amiga, as that's what I need the chips for,
and there are probably lots of Amiga users for whom the info would be
useful.
Thank you all in advance,

Message-ID: <8802100646.AA16770@ucbvax.Berkeley.EDU>
Source record: 254597

This isn't strictly related to the ST, but I thought that the people who recently argued that civilization, yea verily life itself, could not continue without multitasking micros might find this amusing. It's from the "Program Notes" column of the Feb 88 IEEE Spectrum (p19).

Not-quite-MacMultitasking
...
An August press release from Apple Computer Inc. trumpeted the release of MultiFinder, the "first multitasking operating system for the Macintosh." But the software might be more appropriately called cooperative system-sharing.
... (several paragraphs about the restrictions and catches in MultiFinder) ...
Even "Program Notes" was taken in; the column [Spectrum, December 1987, p. 22] claimed MultiFinder was an actual multitasking system. Apple says, however, that operating systems should be driven by the applications' needs, so perhaps true multitasking for the Mac will be relegated to A/UX -- Apple's version of Unix.

From the list of limitations they quote, it sounds like Apple has a ways to go before it catches up to Beckmeyer's line...
I still don't like the wimpy pseudo-multitasking like Amiga and Unix push. I prefer real multitasking, where each process has its own processor! But I've got a lot more soldering before I get there...

1700. Tried to 1 meg, problem

Newsgroup: comp.sys.atari.st
Date: 1988-02-10 08:25:21 UTC
From: chad@byuvax.bitnet
Message-ID: <113chad@byuvax.bitnet>
Source record: 254600

I just finished putting in sockets, the capacitors, and 2 resistors
on my 520STfm motherboard (rev D) where it normally is in a 1040.

Now, with or without the sockets populated, you turn the machine on, it
displays that typical blank screen for boot but with a white stripe
going across it about 2/3 or 3/4 of the way down from the top

```
----------------

++++++
++++++++++

----------------
```

with some dark pixels on the bottom of the stripe. When one turns it off
and on again, one gets rows of a dark pixel pattern (blotches in a pattern)
on this same screen. (Guess that the video RAM gets junk in it.)
The disk drive is NOT accessed. It just sort is dead. I've looked at all
the traces on the board, can't see anything shorted, etc.

Any suggestions?

Thanks,
Chad

> turn an oxymoron (intellectual property) into a reality. As usual,
> when a law tries to change reality, it gets ignored. Expecting
> anything else is silly.

The law is set up to recognize the reality of intellectual property. Without such recognition, there's no way to protect those who create any work of creativity - be it a painting, a novel, or a spreadsheet program - from those who would rip it off and claim it as their own. Laws are only ignored by the unlawful. It may be silly to expect that people obey the law, but I still hope...

> BTW - I *don't* condone stealing software.

You've sure spent a lot of net.bits arguing for it, though...

> While it's not immoral, it
> *is* unfair and dishonest.

I'd argue that it is immoral, just like other forms of theft, but trying to argue that point with you is pointless, since you don't see it as property to be stolen.

Can I piggy back another set of 256K chips in my 1040 ST? I opened it up, there seems to be plenty of room (see below for sad story). In my opinion, $120 is FAR to much for one of those kits with no RAM chips.

Has anyone tried this? If so, how do I go about wiring the new bank of chips in? I am not afraid to solder and cut, but my hardware knowledge is not extensive enough to know WHAT to solder and cut. Any information or pointers to information would be much appreciated.

Now for a sad story: I opened up the ST's case and removed the RF sheild. Then I realized I forgot to ground myself! OH SH**! It was too late... when I powered up again, all I got were green and white stripes on the monitor. So, in an attempt to see if I could save myself some money, I have spent more. I'll be talking to my dealer today to assess the damage.

P.S. If this is getting out there, please let me know. I'm not sure if all of my postings and mail are getting out.

From: crash@calgary.UUCP
Message-ID: <1341@vaxb.calgary.UUCP>
Source record: 254504

Hi,

This is for all those asking for more info: (in rough form)

2.1 Definition of Project

The project consists of the construction of an external ram disk that interfaces to the ATARI ST computer family. This consists of a custom chip that implements directly the communication with the ATARI ST over the hard disk interface. It will implement the hardware handshaking of the hardisk interface and will interpet the low level commands required for data transfer. The chip will also directly control and access the ram disk memory. Two types of memory chips can be controlled, 256K chips and 1meg chips. The maximum memory for the ram disk is 2meg or 8meg. The two types of memory cannot be intermixed.

The project must also allow hard disks that normally use this interface to continue doing so. This invloves buffering of the hardware interface with TTL drivers. Other inclusions that should be consisdered are:

o software driver resident in the ATARI ST

o memory test (hardware or via the driver)

o battery backup of memory <- not viable

o the ram disk has it's own power source

A pcb is being made that supports the 256K chips. Initial versions of the ram disk will be offered in kit form (chip and pcb).

No pricing yet, sorry.

>The Atari ST to SCART adaptor sounds interesting, but would it provide BOTH rf &
Ther is a great difference in the technique:

The Euro-AV (SCART) includes extra lines for almost evey signal a TV can
handle: one for each:red, green, blue, horizontal-sync, vertical-sync,
composite-sync, composite video and so on.

Composite video (or FBAS in Germany) contains the complete picture on a
single line: it is the signal the modulator will put on top of the RF
and make it look like coming from an antenna.
The ST has outputs for RGB and composite-sync (sync not video!). The
RGB-compVid-Converter will have to put this information on a sigle line,
whitch is a tricky task. But the Motorola MC1377-chip (you will find one
opening your video camera or Amiga) solves this problem. Here in Germany
a Magazine (c't) published a board containig this chip and a little more
(resistors, capacitators) to get composite video.

A simple solution ist mixing RGB and compSync together by a resistor
network: connect 300 Ohms to each, red green and blue, 50 Ohms to
composite sync and solder the open ends together; what you will get is
an grey-scale video signal of the medium or low resolution; I am using
this to display all the colour-games on a green monitor. Not the
solution but cheap...

In article <833@aucs.UUCP>, 870646c@aucs.UUCP (barry comer) writes:
> ..... I am wondering what is the latest version of
> Forthmacs, I have received version 1.0? If I cannot find a legal copy of
> Mach-2 Forth, I will have to use the Forthmacs(which seems to be a nice
> version of Forth).

I have ForthMacs version 1.1. However, I got it about 1 1/2 years ago. If you want, I can post the README file for it.

If there is a newer version out there, I'd like to see it. One minor big is that if you hit the delete key at the end of the line too many times, it bombs.

later,

Maurice

In response to a query by Ted Bailey:

> Is there an update to DBMan v.2.02, and is there an "assist" style
> GEM interface available? (Neil??)

I don't know about the version marketed by Atari, but Versasoft released version 3 a year ago and has just released version 4. There are many enhancements, including variable length text fields, private variables and parameters to command procedures, browse and shop commands, ability to save and restore screens, GEM-style menus and file selector boxes, many new functions, various changes to make it more like dBASE III, a few bug fixes (but there weren't many bugs to start with) and yes, an "assist" program that you can run, implemented as a DBMan command file.

Just a word or two about MWC V3.0 --

Due to some delays (a disk crash and a bit of slowness on my
part), Version 3.0 will not ship until around the first of
March, 1988. We are in Beta testing now, and unless anything
untoward happens, we should easily meet that date.

Version 3.0 comes with the following features not found in
earlier versions of MWC --

CSD (C Source Debugger) support

GEM Resource Editor

Improved code generation including optional
PC relative code generation.

Improved utilities:

as68toas now is more complete and robust

db handles symbol tables > 64k and supports
new options for GEM program debugging and
debugging from a terminal connected to the
AUX port.

msh has an expanded internal string pool and
many fewer "assert failed" type fatal conditions.
Also, some built-in commands have been improved.

nm handles large symbol tables.

Improved compilation and assembly speed.

Improved diagnostics from the linker.

The C Source Debugger, CSD, will ship at the same time. It is
similar to the CSD product that Mark Williams has sold on the
IBM PC for many years.

MWC has been advertising Version 3.0. I called about it the other day.
It is to be ready for shipment in 4 to 6 weeks. Owners of previous versions
will have to pay about $30-$40 (didn't remember the exact figure, sorry)
for the new version. It sports a resource editor and a C source debugger,
in which you are supposed to be given a certain amount of interactive
(interpretter) ability to debug your program.

1712. CP/M on the ST

Newsgroup: comp.sys.atari.st
Date: 1988-02-10 22:34:32 UTC
From: pchris@sim.Berkeley.EDU
Message-ID: <666@pasteur.Berkeley.Edu>
Source record: 254513

I recently downloaded Atari's ST CP/M emulator (I want it for writing assembly code for Z80 hardware controllers). Unfortunately, it doesn't work with my standard ramdisk. Does anybody know of a ramdisk that allows CP/M formats? Also, are there any good Z80 assemblers, C compilers, and text editors in the CP/M world (Public Domain?)? And finally, does anbody know of CP/M BBS's in the Bay Area?

Thanks for any help you can provide.

Chris Perleberg

From: david@bdt.UUCP
Message-ID: <134@bdt.UUCP>
Source record: 254514

I do a lot of transfering around between systems. I've found that when the disk is formatted on the PC with MS-DOG 3.2, the ST can read-write the floppies fine if both systems only use the root directory. For some reason if a mkdir is done on the PC, the ST sometimes can't find the directory or the files in it. And occasionally, TOS will make the disk unusable be both systems when I try to copy a new file to the disk.

From: Thomas_E_Zerucha@cup.portal.com
Message-ID: <3112@cup.portal.com>
Source record: 254519

The Austin Code Works (advertises in Doctor Dobbs and elsewhere) has DNA and protein data on disk with extraction programs - but they have source to all of their programs, so you should be able to compile them if you have a C compiler for the ST. They can even do some ST formats of disk, I converted their KSTfonts to GDOS. (512) 258 0785. (acw!info@uunet.uu.net - according to their ad.). They do charge for the source and data though.

1719. Neural Network Simulators on the ST..?

From: ee_tw@ux63.bath.ac.uk
Message-ID: <2166@bath63.ux63.bath.ac.uk>
Source record: 254523

Does any one have any source or some more details of how to encode images in the GEM .IMG format ?. I have programs that will convert screens etc into the right format but I would like to be able to do it directly.

Also can any one tell me why .GEM pictures from easydraw 2.0 won't load into ventura running on an IBM. What seems to happen is that the sizes are not set correctly also line widths appear different. Experiments with a version of GEM Draw on the Atari seem to work but one cannot do very large ie a lot of lines with the version I tried.

Any help would be much appreciated.

==========
ZMAGAZINE NEWSWIRE
==========

DATELINE: 1-27-88

GOOD NEWS FOR ATARI OWNERS!

ICD, Inc. and OSS, Inc. (Optimized Systems Software) have just signed an agreement which will "add new life to all Atari computers". Under this agreement, ICD will add the manufacture, marketing, and support of all current OSS software titles for Atari computers to ICD's already powerful Atari product line.

ICD's friendly, helpful staff is now trained in all aspects of support for the complete OSS product line including:

MAC/65
MAC/65 Toolkit
ACTION!

ACTION! Toolkit
BASIC XL
BASIC XL Toolkit
BASIC XE
Writer's Tool
DOS XL
Personal PASCAL for the Atari ST

Ordering and support for ICD/OSS products are available by calling 815/968-2228 from 8AM to 5PM CST Monday through Friday. Support is also available 24 hours a day 7 days a week on the following Electronic Bulletin Boards:

ICD/OSS BBS 815/968-2229 300-9600 baud, CompuServe,GEnie, Delphi, and BIX. ICD's 24 hour FAX is connected to 815/968-6888.

The San Jose, CA numbers for OSS will no longer be providing support. Orders for OSS products may be placed now. All products will be shipping in quantities soon. For more information call any of our product support lines or write to:

1727. GEM Metafile to PostScript conversion - new version of mfps

Newsgroup: comp.sys.atari.st
Date: 1988-02-11 18:52:29 UTC
From: axel@coma.UUCP
Message-ID: <340@coma.UUCP>
Source record: 254528
Cross-posted to: comp.sys.atari.st,comp.text

More than a year ago, I posted the first version of 'mfps', my GEM Metafile to PostScript conversion utility to comp.sys.atari.st. The reception was positive enough that I continued working on the program. Today, I'm posting a new version of the program which has a number of bugs fixed and several new features. Most important are the extensions to the way text objects are handeled, and the support for Adobe's 'Encapsulated PostScript File format' (EPSF). EPSF is the basis for linking PostScript images into the output of your favorite word-processor. Well, right now, this statement may be a bit overdrawn but some day in the near future it will be valid. However, at a number of sites, mfps is in daily use to incorporate images created with GemDraw and EasyDraw into TeX and Troff formatted documents. If there's enough interest, I'd be willing to post a set of TeX macros that do the job for the 'dvi2ps' PostScript driver. For Troff there are some more problems to handle.

Originally, I intended to publish the program in comp.binaries.atari.st but the moderator (turner@daisy) seems to be away (Hey, Jim are you still out there ???).

The Posting consists of 5 parts. Together, these parts make up a uuencoded .arc file. For people, who like to upload their metafiles to a UNIX machine, there's also a UNIX version of mfps available on special request.

>>> When you prepare the five parts of the posting for unpacking, don't
>>> forget to delete the .signature-s at the end of each part.

enjoy, Axel.

So, here are the checksums:

```
Name Length Stowage SF Size now Date Time CRC

```

And this is the README:
This program enables you to combine the advantages of object oriented
drawing (e.g. with GEM-draw) with the wonderful capabilities of
PostScript printing devices (e.g. the Apple LaserWriter).

If you're interested in the structure of VDI-metafiles, you'll with
'mdump' find a utility to print metafiles in a human readable form.

The package consists of three programs:

- mfps, program to convert VDI-metafiles to PostScript

- mdump, this is a link to mfps. When called, it prints
a human readable representation of the metafile.

- fitps, to change size and position of PostScript graphics.

COPYRIGHT NOTICE:
'mfps', 'fitps' and 'mdump' are copyrighted by the author. Permission is
granted to copy and distribute the programs without charge provided
this copyright notice is included in the copy.

IMPORTANT:
If you are planning to use mfps, fitps or mdump please send me a note.
I'll try to maintain the the programs as well as possible (i.e. as my
spare-time allows). All bug-reports and - of course - bug-fixes, as
well as suggestions for improvements are most appreciated.

>>Has anybody seen or heard anything about the new HP DeskJet
>>Laser Quality printer?
>> OK, but what kind
>>of printer driver would I need? Is it Epson FX compatible
>>or what?

With the FX-80 emulation cartridge, list price $75, it is FX-80
compatible. Graphics is scaled by the emulation cartridge to print
the same resolution as the Epson.

>> Will I able to print output from EZ-Draw with the
>>standard driver and get laser quality? If anyone has any
>>more information on this new product please let me know.

Graphics, since it's the same resolution, will be just as coarse as
the Epson. Text prints at 300 dpi and is laser quality.

1730. is there English documentation for TEMPLMON?

Newsgroup: comp.sys.atari.st
Date: 1988-02-11 20:33:50 UTC
From: egisin@watmath.waterloo.edu
Message-ID: <16892@watmath.waterloo.edu>
Source record: 254531

TEMPLMON is a resident debugger like MONST, but much better.
It doesn't crash when you disassemble code, for example.

However the only documentation is a German help message.
Is there a version with English help, or some English documentation?
I am mostly interested in the description of trace mode, the rest is simple.

[some may consider the use of ALT-HELP to enter the debugger a bug,
but I don't have a printer :-}]

/ hpvcla:comp.sys.atari.st / keithr@vice.TEK.COM (Keith Rast) / 11:23 am Feb 9, 1988 /

Has anybody seen or heard anything about the new HP DeskJet
Laser Quality printer? I just read an article on it in the
newspaper, but it didn't give enough specifics. It did
say that it was $995, 300 dots per inch, two pages per minute,
uses a replacable ink jet head ($18.95) thats good for
about 600 pages, it uses regular paper. The article also
said that it was HP and IBM compatible. OK, but what kind
of printer driver would I need? Is it Epson FX compatible
or what? Will I able to print output from EZ-Draw with the
standard driver and get laser quality? If anyone has any
more information on this new product please let me know.

keithr@vice.TEK.COM

1732. Mark Johnson C

Newsgroup: comp.sys.atari.st
Date: 1988-02-11 21:35:29 UTC
From: egisin@watmath.waterloo.edu
Message-ID: <16898@watmath.waterloo.edu>
Source record: 254533

There are several problems with the Mark Johnson C compiler.
The preprocessor doesn't do macro expansion correctly.
There are a few code generation bugs, and the C library
is missing some things and has a few bugs.
It is also missing goto which is commonly used.

I used to have Mark's (new) mail address, but I can't reach him any more.
The last I heard he was working on rewriting macro expansion,
but I don't know when and if this will be released.

I've documented the compiler bugs I know about so others can avoid them.
To get around the other problems I have a couple of solutions.

I found a public domain preprocessor (decus) I almost have working and will post
a binary when I've tested it for a while. It also has #if, #elif and #assert.
(this is a 140K program I've compiled with MJC with only ~10 changes.
I did have to preprocess it under Unix cpp though.)

I wrote a short preprocessor to handle goto's by generating asm() statements,
which I will post as source to this group.

I suspect others have fixed things in LIB.C themselves.
If people send me fixes I'll try to merge them
and post a set of context diffs based on the original.
(I've fixed redirection and made some small extentions).

Eric Gisin, egisin@Waterloo.EDU, watmath!egisin.

Compiler bugs:

pointer-to-function types can not be declared (in general).
sizeof((*)()) and typedef (F*)() don't work.

expressions with && and || will generate incorrect code.
to work around this parenthesise the && subexpressions, for example
a && b || c --> (a && b) || c

multiple structure assignment (a = b = c) doesn't work.

when using combined operator assignments (+=, etc) the left side is evaluated
twice, not once (for example, *p++ |= BITS increments twice).

Documented features that cause many problems:

the type of initialization variables must not be (char)
and initialization values must have matching length (short or long).
I found this the most time-consuming problem in porting code.
grep all C files for '=.{' looking for char variables or structure components.

often you can change char to short.
look for things like "long STKSIZ = 4096" and use 4096L.
also make sure NULL is defined as 0L, not 0.

This last bit makes it worthless, unless you can tell us how to tell if
we are getting a ^C or a Pterm(). Of course, ^C still isn't worth much
even so since it is not an interrupt but a polled event (polled by calls
to the gemdos cooked routines) but it would be worth something then.

It sounds like a patch from Allen's comments about it being ouragously large
and maybe needing FLDR???.PRG as well.

You know. It strikes me that this should have been very simple to fix.
You just have the HD device driver do mediach() events.

Yup. Atari has developed the commodity computer system. Every month or so you get to buy a new version of the ROMs. The systems themselves they will sell at no profit and they wil make a fortune selling ROM revisions. :-)

Actually, I think they should make a RAM loaded patch and post it here, DELPHI, GENIE, COMPUSERVE (open forums not the developers SIG), the STadel network and any other of the major computer networks.

Rumor has it that Lyco and CMO were buying "bad" STs from Atari,
ostensibly for spare parts, and then doing whatever it took to make
them run enough to sell them. You pop off the cover and the RF shield
and there are Atari Q/C "REJECTED" stickers all over the place. If
Atari shut them down from doing this, it's one of the BEST things I've
heard of Atari Corp. doing in quite some time.

It would seem that Atari is abandoning GEMDOS as well. A.P. has fixed
much of what is wrong with it, and there are rumors of a disk OS being
distributed to developers for testing, but Atari still hasn't gotten
the blitter ROMS out to the unwashed masses yet.

Andy Tanenbaum has said he should have the ST version of Minix out
some time this spring. I may never go back to GEMDOS. Anything I
don't like about Minix, I can fix, or add!

P.S. - Landon, what does Apple have you working on? An ST emulator
for the Mac II? :-)

In post <1012@sask.UUCP>, long@sask.UUCP (Warren Long) says:
!
!This is a complaint about the 'protection' used by one author for
!his shareware product:
!
!> Perhaps the worst I have ever seen of this type is a program, DS, a
!> progam to help move, delete, copy, etc. files on hard disks. While the
!> program was quite good, and the request for money was small ($15), the
!> program had a 10 second delay at the beginning and the end of a run.
!> Instructions for disabling this pause were available only after you
!> coughed up the $15. This, to me, is a type of blackmail. Since the
!> use of this program is to be a quick utility that works faster and
!> easier than DOS commands, a delay like this was way out of line.
!> Needless to say, I don't use the program, and would never suggest that
!> anyone else do.
!
!I am impressed with the method used, and am surprised at the audacity
!of the above user. The author has found a very clever way of
!protecting his SHAREWARE product, which allows a user to sample the
!product, yet requires an end-user to pay IF and only IF he/she intends
!to use it regularly.

First off, _I_ am the above user. Please be sure to attribute your
quotes....

My complaint with this program is, I think, made clear. This util. is
designed to be a quicker and easier way of managing a hard disk. Placing
pauses of that length (10 seconds is LONG time), defeats that purpose. It's
much like marketing a shareware wordprocesor, but you can only use the
'save' function if you send me $20 bucks.

Let's comapare this to the plea for money used by ZCOMM, a shareware
telecommunications package. This program beeps and displays a
copyright/send-money mesage at startup. I need to hit a key before I can
use the program. Upon payment, I can get this feature disabled. This
not-sp-gentle reminder does not interfer with the actual use of the program,
it simply beats me over the head. I will be registering my copy of ZCOMM
shortly (when Unca' Sam sends me my refund. Can you say broke :^), and in
the meantime I can use the program to its full extent (well, almost.
Registering gets you some bells+whistles too).

>to it ring. Would you happen to know if they have a real phone number?
>Thanks for your help again.
>
>T. Bailey

The number was changed to (408) 268-6101. BTW, I received a flyer
some time ago notifying me of another upgrade. The new version is 4.00,
and it's basically dBASE III+ compatible ("most dBASE III+ applications will
run without modifications"). Also, they mentioned that a compiler will be
"coming soon."

I won't go into features, being wary of the notorious net.police
out there and not wanting to make this an advertisement for VersaSoft. But
the prices for the upgrade are:

from 2.x to 4.0: Interpreter $80 US; Run time $70 US
from 3.x to 4.0: Interpreter $45 US; Run time $40 US.

And if you upgraded from 2.x to 3.x anytime after Sept. 1, 1987, the upgrade
cost is $30.05.

I am in the process of bringing up a Neural Network Simulator on the ST.
The source is in Modula-2 and was posted to the net a few weeks ago. It
looks very promising as I believe the code is portable. I will be using
TDI's Modula-2. If you want more info on my progress please send me
e-mail.

Will the Resource Construction set be integrated into the C comipler and the debugger? Will there be an easy way to integrate resource files automatically within C code itself (so I won't have to use separate .rsc files)?

> say what his magazine was.

And this was probably three quarters of the people who ever saw the program.

There is one aspect of SHAREWARE people are ignoring. If your program
isn't getting into the hands of the people who might want it then you are
not going to get anything back from it.

If you want your shareware to succeed, then send it to EVERY magazine software
reviewer you can find, have heard of, or is even rumoured to exist. Upload it
to GENIE, COMPUSERVE, etc. Call into bulletin boards across the country
and upload it. Post it to usenet. When people make queries about applications
it can fulfill take the initiative and send them a copy on appropriate
medium. Find a system manufacturer and get them to distribute it with new
system purchases. Go into book stores and stick free copies of your software
into the magazines for the appropriate system. Get software and bookstore
sellers of software to give your software away with other purchases, or just
give it away as good will for people browsing in their stores.

Yes a lot of these suggestions involve some cost. But the original shareware
successes were never without cost to the producers either. If nothing else
a shareware success has got to have some kind of support, and it has got to
be obvious to the casual reviewer of the product that you do give this support.

Recently, stowe@silver.UUCP (Holly Stowe) said;

> I don't know of 'vi' for the ST, but can I interest you in a nice Emacs?

There are a couple of vi-alikes for the ST that I know about;
there's STEVIE, which I've never used but I've heard has about 50% of the
vi command set, and there's LEVEE, which I wrote, which implements about
80% of the vi command set (and has other neat things, too, like counts on
macros and `~'....)

Geez, Holly, you should know that* -- the last STadel distribution I sent
you has a copy of the LEVEE executables/docs in it. Geez, some people's
kids... :-)

Two --> resistors ??? <--

I just completed a 520STfm upgrade. Used sockets, caps and of course
chips. No resistors though. Where did you put the resisors ??? I also did
the upgrade on a Rev D board.

>
>Now, with or without the sockets populated, you turn the machine on, it
>displays that typical blank screen for boot but with a white stripe

Sounds like you ZAPed someting while you were working on the upgrade.
I would look into the MMU if I were you. You may have toasted it. Sounds like
what your seeing is some words placed on the screen. A friend of mine had this
with his upgrade board, and the problem WAS the MMU. Replaced and allis fine.

From: wes@wsccs.UUCP
Message-ID: <134@wsccs.UUCP>
Source record: 254455

Neil Harris (or anyone at Atari):

Is there anything more you can tell us about this 68030-based system?
(Other than it will be announced/released/showed at the Hanover Fair.)
Is this the fabled "TT" computer? How much memory, disk space, I/O
connectors, bus slots, serial ports, and etc does it have? Does it have
graphics, or will we be plugging our ST's into it as the console?

(OK, OK, I realize this was a waste of time, but I *HAD* to ask).

Frozen keyboard? Here is my defroster:

When I put my ST in a PC-housing (1 year ago) I wanted to have a long keyboard cable.
Because this cable wasn't shielded in version 1 I had the same problem; sometimes the keyboard processor ran into nirwana.

I cut the RESET line that connects ST and keyboard reset, put a RC-combination into the keyboard (1 kOhms to +5V, 1 Microfarads to ground) and gave both a reset button.

This will cause some new problems that can be solved by a switch. If Your keyboard is locked, disconnect motherboard and keyboard reset, reset the keyboard and connect them again. Work whithout trouble for 10 month now.

Effective immediate and until early May, the response time for the uupc and uupc-request mailboxes at van-bc will be *VERY* slow, due to a severe lack of spare time on our part. (This mean that it is highly unlikely that we will be able to reply to *most* of these mail before May.)

Sorry for any inconvenience this might cause.

Hopefully things will once again pickup when we get to the month of May.

In the mean time, you are advised that your UUPC related information *might* be better shared among interested people if it is posted to the comp.mail.uucp newsgroup.

How is integration of resources into programs currently done? So far, all my programs have to have a .rsc file. I know there is a way (since plenty of programs out there don't seem to have one), but I'm ignorant of the way.

Teach me oh masterful ones...

One of the people on this board (Chuck Purcell) has already cleaned up
the Mark Williams Version (right Chuck?) If there is enough interest,
I am sure I can get him to post it.

> If I find any differences for the Mark Williams C I will fix them
>and repost the new files (any that are changed) to the net.

No need. I think Chuck already fixed all that up. There were some
things that needed changing if I remember correctly.

-Todd Burkey
trb@stag.UUCP

P.S. No, I am not going to use curses on the next HDSCAN version for
the ST...just because the Unix version (posted last month to
comp.sources.misc) had it doesn't mean I am sold on using it. I still
feel it is more trouble than it is worth to cripple a program on
a graphics computer by using curses. Oh yes, HDSCAN 1.4/2.4 is
completed and undergoing some last minute touchups. I will be posting
the 1.4 version to the net if I get sufficient interest. I was going
to wait for the 3.0 version of MWC, but now it looks like that will be
for future versions. I am also getting ready to release an
intermediate version of DISKTOP that supports more disks/files. I know
it has been a long time, but I have been thinking of converting the
whole DISKTOP program over to MWC so I can use HDSCAN's FAT scanning
routines (I have LOTS of floppies and really want to minimize the time
I spend catalogging them.) This HDSCAN-like version of DISKTOP will be
next on the agenda...

1763. Re: Guidelines on legal protection for shareware & freeware

Newsgroup: comp.sys.atari.st
Date: 1988-02-14 07:39:49 UTC
From: kraut@ut-emx.UUCP
Message-ID: <810@ut-emx.UUCP>
Source record: 254463
Cross-posted to: comp.sys.amiga,comp.sys.misc,comp.sys.ibm.pc,comp.sys.mac,comp.sys.atari.st,misc.legal

for those of you with a serious interest in an up-to-date analysis of
the current legal situation, you may want to get hold of a copy of a
publication put out by Micro Analyst Inc.:

"SOFTWARE LEGAL ISSUES FOR MICROCOMPUTER USERS AND DEVELOPERS"

It is being sold for $20 and can be ordered from Micro Analyst,
P.O. Box 15003, Austin TX 78761, phone (512) 926-4527.

I believe that the publication is an outgrowth of graduate research work
done by the author under the guidence of a respected legal expert in the
field of computer-related law here at the University of Texas (Professor
Michael Kirk-Duggan). I am no lawyer myself and neither is the author,
but I feel that the price is a worthwhile investment for anyone either
writing or using software commercially. If you are writing software, it
will prepare you to have shorter and more meaningful discussions with
your lawyers; and if you use software in your business, it will help
you understand better what your rights and liabilities really are.

The Table of Contents includes sections on the following topics:

- the rights of software owners
(backing up software legally; employer liability)

- laws affecting software users and developers
(new legislation passed in 1986 and their limitations; state laws)

- current court cases deciding the law
(background and current cases)

- information needed to market or purchase software
(purchasing and publishing software - sale or license; legal protection;
security)

- protecting published software
(copyright protection without filing; registering software; trade
secret protection; contracts; patents, trademarks and service marks)

- marketing or buying software abroad

- Appendices include information on ADAPSO, a chronology and discussion of
recent computer cases; copyright registration form and instructions.

- a 3-page bibliography

Disclaimer (or should I say "Claimer"?!): The author is a friend of mine but
our only business relationship is that I am a satisfied customer of

Micro Analyst Inc.

<note: below follows a description of the book as taken from an adver-
tising flyer from Micro Analyst>

SOFTWARE LEGAL ISSUES FOR MICROCOMPUTER USERS AND DEVELOPERS
==========
(by Mary Herbst, Copyright August 1987)

This book looks at legal issues of concern for both software users and
developers. The scope is limited to microcomputer software and thus is
targeted especially for them.

Topics covered include the current state of legislation regulating the
software industry, as well as recent court decisions.
Licences, copyrights, patents, and the rights of both users and developers
are discussed.

The format of the book is general enough for anyone to understand while
technically accurate so as to provide clear concise information.

Hi!

Just these days I am about to decide what to do with a program I am writing now. It is supposed to be a super-duper-terminal (although now it is far beyond of being that :-).
I released a Version 0.9 to the PD. In the poster I told people to write if they were interested in the Version 1.0. At this time I intended to make the 1.0 shareware (say for $20). The results were NULL. On the other side all people who I know personally, who saw the program told me not to be so stupid to give it away. "Don't be stupid, sell it!".
So now, I am about to decide to sell it. The message about the postscript-driver was a further hint in this direction. I think Share-ware is a good concept, but people are not build for it.

Urs, Markus

PS: If anyone likes to test the 0.9 let me hear.
PPS: Could anyone mail me the address of Fred Fish?

Hi folks,

Could somebody please tell me if there is a librarian available for the Lattice C 3.04 compiler?

I tried to use the librarian of the Megamac C compiler on the libraries ending on .O without succes.

Does someone know the format of the *.bin object files and the format of the *.bin libraries supplied with the compiler? Perhaps it would be possible to write my own librarian.

Thanks in advance,

Victor Ronnen

Earn: FKERONNE@HLERUL52

P.S. Please send your messages to the net, I think that other people will also be interested in this topic.

You can take the data structure that is the .rsc file and declare it as a data structure within the program itself (you have to do things for the various resolutions though, which loading a .rsc file does for you). Some Resource construction sets will output the actual C or assembler code of the resource that you can include or merge with the other source.

Regarding Megamax, I gave them a call on 02/11/88 and was told that my disks and money were received and that the disks would go out in the mail this week, but without docs.

I have a question for either the Megamax people or someone who has Laser C: does the inline assembler now support the * or ORG directive. i.e. Can the assmebler jump around the code segment? And there is no code segment size limit, right? The ads also say that Laser C now produces absolute code. Does this mean that jumps tables will now actually contain the real address of a routine, and not a pointer to yet another JMP statement. This is what Megamax currently does, and it's a time and space waster, not to mention that it complicated jump table code.

Regarding the shareware discussion. I'm planning to release the next major version of the 8 bit emulator as shareware. I figure it's easy for most people to access, and they don't have to wait eons for a certain unnamed magazine to publish. However, the discussion didn't give shareware such a good reputation. I'm just wondering if anyone reading this has ever released anything as shareware, and what kind of response they had. There must be _some_ good stories?!?!? I'm spending about a thousand hours on this new version, and I want some kind of a payback.
So let's hear more pros and cons regarding shareware.

I have, and for a Commodore 64 programme no less! (or is it "no more"?)
It was a total of $30, for the 6485 BBS way back in '86.

And I made money off my own "MacDoodle 1.3", which I took in about
$50 for.

1774. file limits of root directories

Newsgroup: comp.sys.atari.st
Date: 1988-02-15 04:32:13 UTC
From: gpm@dukempd.UUCP
Message-ID: <449@dukempd.UUCP>
Source record: 254474

I was trying to download a fortran library to the ST over a modem using Uniterm's kermit. Kermit was writing the files to the root directory of the ST's disk drive when I ran into a problem. After writing the first 100 files with no problem, the kermit couldn't open the next destination file. After the 100th file the default destination extension suddenly changed from ".F" to ".KK1". Then a message appeared proclaiming the kermit unable to open the file. I changed the destination path to the root on the ram disk and downloaded a few more subroutines. Copying these to the disk drive didn't work either, failing with the same complaint. Lack of space was not the problem as the disk was formatted to 830k and the first 100 subroutines only took up about 150k.

I "solved" this problem by putting all the routines into a subdirectory Once the subdirectory became the destination directory, kermit could open and transfer the rest of the files--about 100 more--directly without any more flak from the ST.

Question: is there a 100 file limit on root directories? And if so, why doesn't it extend to the branches as well? Did I run up against a real snag in TOS; is this related to the "40 folder limit", which I believed to be a problem only with hard drives? I tried on several different occasions to break the 100 file barrier on the root directly before I gave up.

1775. Re: Free RTX (or maybe almost)

Newsgroup: comp.sys.atari.st
Date: 1988-02-15 04:47:45 UTC
From: preston@felix.UUCP
Message-ID: <21215@felix.UUCP>
Source record: 254475

>> One question - is RTX any good ? Do we really want it in the public domain
>> or will it end up a dog like GEM ?

A good question. I bought the first version of the MT C-shell (that is built on top of RTX). At the time I didn't have a hard disk, and the shell hit the disk fairly often in normal operation. As a result it was way to slow to be useful.

Beckmeyer sent out an update notice several months ago, and I bought the MT C-Shell update (version 1.10), the Micro C-Shell, and the Hard Disk Accelerator.

The hard disk accelerator seems to do a fairly good job of eliminating all those extra disk accesses that TOS usually makes. It is always installed on my hard disk and is generally fairly ignorable :-)

The Micro C-shell is also a fairly good product. I tend to switch between it and Gulam about equally. (Gulam doesn't do pipes, among other things).

After David Beckmeyer's posting I tried running the MT C-Shell software in a previously empty partition on my hard disk.

I ran it for a short while.

- Screen (text) output seemed a bit slow.

- Interaction response is slow and jerky with programs running in background. To be fair, this may be due to the ST BIOS implementation.

- The whole thing crashed after about 5-10 minutes of use. I don't know why and didn't try to find out.

My \auto\ folder installs, in order, a 100K 'eternal' ramdisk, the beckmeyer hard disk accelerator, and Gemboot (a 40 folder bug workaround).

I'd be interested in hearing experiences from other people who have tried RTX and/or the MT C-Shell.

Fffhew, great idea. Ever thought about disk caching?

I happen to have a 1.2 MegaByte disk cache installed, always. I would hate to see your 'solution' causing my cache to be invalidated. It is already a pain in the neck that GemDos returns media changed on every other access to a write protected floppy...

About the resistors. The people (many) who gave me instruction on how to do it all mentioned resisitors needing to be put in. On the REV D board there are 4 68-69ohm resistors as follows

-***-
-***-
-***-

-***-
and then 9 or so 330ohm
-***-
etc.

The two I put in were in that space there in the 4 and underneath the 4 68-69 ohm type. We looked at a 1040STf REV B board (which is totally laid out on the board differently -- RAM, not ROM under power supply, CPU not on right, etc.) and it two had 6 (not 4) 68-69 ohm resiistors and 9 or so 330 ohm resistors with the RAM. Someone told me the resistors are there to be nice to the MMU chips and that some early 520 ST models didn;t have them but they do now.

We are going to first try reseating the MMU and then try to get one. (anybody have one cheap???)

Chad

Whatever you do: A mediach to a hard disk can be rather destructive:

All open files, half written etc, all modified but not yet written FAT clusters and more is lost when a media change is sensed by Gemdos. Gemdos does use some limited caching, especially for FATs.

If you like to execute a mediachange (well... simulate one) you need to control the circumstances rather well and make absolutely sure there is nothing hanging around anymore.
The FATs can be taken care of by executing a Dfree before and after the change operation, while the rest is reasonably safe when a directory with more than 32 files is listed (before and after!).

I do prefer foldrxxx because I don't like to make the one fatal mistake that blows up my disk, and also the trick with the media change has to be executed regularly, so one has to monitor the folder limit continuously.

<Thomas_E_Zerucha@cup.portal.com> writes...
> Arkanoid uses a series of locations where GEM stores the current mouse
> X,Y, and button state, somewhere in 0x00002000 - 0x00002fff range, and
> you can find the locations easily and patch them. I have the new ROMs
> and a copy of ARKANOIDS that runs on them. When will programmers use
> the documented methods of doing these things <groan>?

I picked up some information a while ago about these values actually being referencable as an offset from the a-line base address (like lots of other information posted in Bammi's ALINE2.H). I haven't tested these values on the Megas, but they should work. Perhaps someone could substantiate their usefulness (or failure) on the Mega ROMs.

```
#define MOUSEX *((WORD *)((char *)aline + (char *)-344L))
#define MOUSEY *((WORD *)((char *)aline + (char *)-342L))
#define MOUSESTATE *((BYTE *)((char *)aline + (char *)-348L))
```

The mouse buttons appear to be (MOUSESTATE & 1) for left and (MOUSESTATE & 2) for right. The higher order bits of MOUSESTATE seem to hacve something to do with the mouse being moved. If anyone can expand on this information, (or make corrections) please do.

Yes, there is a fixed limit on files/directory entries for the root
directory, this however has nothing to do with the "40 Folder Bug".
The root directory is just a fixed area after the FAT (file allocation table),
of fixed size. The subdirectories are more like files, and can be dynamic
in size.

The size of the root directory varies with the media and can be changed
when initializing the media, on the atari you can use the "write
boot block xbios call" for floppies. I don't know what the default sizes
are. This is also a limitation in MS-DOS , since that's what filesystem
format TOS uses.

To g. onufer: re: Microsoft Word 4.0

Don't even consider buying another word processor for the PC or ST.
Word is fantastic (ver. 4.0). Having worked at MS, I had a lot of exposure
to Word, so much that I prefer to use it on PC-Ditto rather than running
one of the ST's WPs. Word is so far advanced it's mindblowing.
It has laser printer support (actually, hundreds of printers are supported).
You can run it in text mode (including 43 line EGA) or in hi-res to get
a WYSIWYG display. Unlike Word Imperfect, you can format any word or character
at any time. You can select from dozens of fonts, and a feature called Style
Sheets makes it a joke to use. You create these "styles" and give them a
2 character name, like SO for "stand out" or PT for "paragraph title" etc.
Each style defines the character format, font, paragraph margins, etc.
You type in a paragraph, and press Alt and the 2 letters, and the whole
paragraph gets reformatted. To change the paragraph to a different style,
just press Alt and some other style letters. The beauty of this is that if
you decide that a certain style should change, say, paragraph titles should
be in a different font, all yo do is reformat the style (maybe 5 keystrokes)
and the entire document will get reformatted. FANTASTIC!!!
Also, there is macro support. Store you favorite sequence of keystrokes in
a macro.
Plus, Word can directly import spreadsheet data from Multiplan, Lotus, and
Excel.
The latest issue of PC Magazine, ranks Word 4.0 as #1 (out of 55 tested)
and Word Imperfect as #4. Plus, Word is cheaper.
Did I mention the box and lineoptions. Draw lines and boxes around words and
paragraphs in any of a dozen line styles. Or stick them in style sheets.
Full upward and downward compatibility with Word 3.0 files.
I could rant on and on about Word. Run, don't walk to your local dealer and
buy it today!

To Darin Wayrynen: Re: redirecting output

Yes, it can be done. First though, what does your ASL do? I helped develop
a PD program called ASL which is a super fast (as fast as TEMPUS) file
viewer/printer. It used a set of custom text plotting routines that printed
about 20,000 characters per second. I originally used them in the 8 bit
emulator, and adapted the routines to replace TOS's Bconout routine.
Fortunately, Bconout uses a vector (at $484 I _think, I'd have to look it
up) which points to the character output routine. This is done because during
ESC sequence processing, the VT52 emulator redirects the routine. This is
an easy hook, not requiring you to hook into the TRAP 13 vector, which would
slightly slow down all TRAP 13 calls. Anyway, it worked like a charm.
Listing files from the desktop was considerably faster, but Atari has since
managed to speed up the Bconout routine in the Mega to about the same speed.
If you have a Mega, it's not really worth the trouble to do this, since
you will probably get no speed increase. The problem is that when the routine
is being called a character at a time, the overhead of the TRAP eats up most
of the time. If you are doing from within your own program though, there
is a much greater speedup since yo can call the routine with a JSR instead
of a TRAP.
One thing I didn't try which would work, is to hook the TRAP 13 vector, and
check for the Cconws command. Printing strings of text at a time will get
you closer to the 20,000 chars/sec speed.
Unfortunately, I no longer have the source code to the Bconout replacer.
I only took about an hour to write in Megamax C, and as since mutated into
another program of mine.
But like I said, it can be done, and only takes about an hour to write the
entire program from scratch.

You can include your RSC file into your program.
The RCS program from DRI generates a .C (.RSH) file which
contains the resource structures.

But there is additional work to do: You have to link up the
structures and put a pointer into the global array.

I prefer the usage of a RSC file. It is easier and safer.
I see no advantage if I include the RSC file into the program.~

This is a case where GEMDOS emulates MS-DOS's file system too well. As in MS-DOS, the root directory is different that the others (because in MS-DOS version 1.x there were no subdirectories). The root directory is in a fixed location, and is a fixed length. So, when it's full, it's full.

I released my TRANSFER desk accessory (that supports WXmodem - it got a mention in the Atari Explorer) as shareware requesting $5-$20. I have gotten about $120 - $150 from it. It is not the way to go if you want to do a commercial product.
The reason I released it as shareware is because I needed to create the accessory (actually, the underlying protocols) because at the time, I couldn't get any communication program that did Ymodem Batch and the various other protocols, and since I am a heave PC Pursuiter, I wanted WXmodem so it would run nearly as fast over Telenet as direct. And IBM PC boards support this and many other protocols. I also had to write an autodialer to get by the busies and the general fingerbusting that PC Pursuit usage causes.
Since I thought that others might have use, and that the program was too small to warrant a full blown commercial package, I just released it as shareware instead of PD. I certainly wouldn't do that now, and it is likely that any improvements may be kept to myself. The "as soon as I pay a few more bills..." effect seems to be prevalent.

Source record: 254493

The answer, I believe, is that *all* Atari floppy drives think they are drive 1. This is why you don't have to muck with jumpers when you get an Atari drive, regardless of whether you are using it as a second drive, or as the first drive on an old system with no builtin floppy. The drives are 'daisy-chained', and the select lines will be crossed over inside each drive -- so that when the computer asserts 'Drive 1', the first drive responds. When the computer asserts 'Drive 2', the passthru in the first chained drive passes that to 'Drive 1 select' on its daisy-chained OUTPUT side, so that drive B sees it as a 'Drive 1 select' signal.

So, if you are chaining your 5.25 inch drive in in the normal way (i.e. plugged into the back of drive A if A is external, or plugged into the back of the ST if drive A is internal, you've got to set the jumpers on the 5.25 inch drive so that it thinks it is drive 1.

This is the company that is making the Accelerator board for the ST.

It is a 14mHz board for the ST, time ratings now say the speed increase is about 75% and it does work with PC-Ditto.

I have been told that the board will eventually be running at 16mhz. Twice as fast. That should be real nice with your favorite C compiler, PC-Ditto, Magic Sac (maybe, not tested), XformerII (Atari 800/C64/AppleII emul),and lots of other fun goodies.

I have a friend who has paid the $200 for a beta board and should get it "Real Soon Now."

>debugged ROMs? Would a RAM loaded upgrade be posted to the net or will it
>cost us an arm and a leg? Why not put it in a cartridge?

Because there is better use for the cartridge port: you can use it for a real time
clock, I/O ports (tricky but possible) or (like me) as a 1 Meg-ROMDisk
(booteble of course).

There is a book here in Germany, called The TOS Listing, which has the
sources to Gemdos, Ataris BIOS and XBIOS and AHDI in it (two guys
de-compiled the Blitter-ROMs...).

Here in Berlin we are working on a new version of TOS using theese
sources , but I think Atari will be faster.

Good grief? What are all these questions about "where can I buy RAM chips?" doing here? Pick up any Byte or Computer Shopper and look through the ads! And by the way, 200ns are NOT fast enough for the ST, you need 150ns or better.

Some good sources to start with are:

Microprocessors Unlimited
(918) 267-4961

JDR Microdevices
(800) 538-500 (408) 866-6200

Advanced Computer Products
(800) 854-8230

I.C. Express
(800) 892-8889 (800) 882-8181 in CA

Jameco
(415) 592-8097

They advertise in Byte and Computer Shopeer, by the way. You might want to know that ram chip prices have just about doubled since the first of the year, too.

I don't have Mark Johnson's email address (I don't know if he's even on the net anymore), but I received a letter from him a month ago giving his new home address. It is:

Mark A. Johnson
5315 Holmes Place
Boulder, CO 80303
USA

In the letter, he states that version 1.4 of his C compiler will be out in March on GEnie. He also repeats his offer to send people a copy of the compiler if they send him a formatted disk. Remember, it's shareware.

When I was working at Ohio State University several months ago, I needed to format a Mac hard disk that we put together with an Adaptec 4000 controller. The commercial program we were provided with would not format the unit, and only provided headaches. The day after I advertised the problem on the net, a program arrived via mail from Ephram Vishniac designed to do exactly what we wanted. After following his instructions, the program worked perfectly. Although he had asked for $10, I had the school send out $15; I would have sent $50, but the budget has been severely cut this year and there wasn't room. I am extremely grateful to Mr. Vishniac and other shareware authors who provide a useful service to the computer community.

Thanks to all those who suggested me that I use Moshe Braner's BARREL.PRG
which I found amongst other files in MOSHE.UUE at Houston's ATARINET
server. Thanks especially to Moshe Braner for having written it!!

According to BARREL.DOC, what is saved in the ramdisk is a compressed
SCODE format. After writing to a file, that file needs to be decoded
with SDECODE. What and where is SDECODE? Could someone send it to me?
It does not seem to be on either of the BITNET servers, nor at Houston.

Thanks in advance,

Ralph P. Sobek

P.S. I do not have access to the newsgroups (we don't have news, yet),
just Info-Atari16 Digest. So send to the Digest and/or me.

>No pricing yet, sorry.

Hmm, sounds fine but...
No pricing? Why?

I've got a memory upgrade from a German company called rhotron.
They made a computer called mc68000 in the early days of 68k with 8
slots for expansion.

When Atari came up with the ST, they made a backplane with the slots and
a little logic to interface it to the ST.
I am using this bus system and a 2 Meg DRam-Board for 1 1/2 year now;
I'm really happy having 1 Meg of RAM, 2 Meg RAMDisk (reset resident and
booteble) and still 7 slots left.

Pricing yet: BUS about 400 Deutsche Mark (1$ = 1.7 DM)
2 Meg about 800 Deutsche Mark.

1803. Problems w/uue files at ATARINET (UH-INFO@UHUPVM1.BITNET)

Newsgroup: comp.sys.atari.st
Date: 1988-02-16 18:06:52 UTC
From: ralph@lasso.UUCP
Message-ID: <8802161806.AA08176@lasso.laas.fr>
Source record: 254353

I've recently downloaded a number of programs from ATARINET. Three of them
had ARC problems; both UUDECODE and ARC were executed on my ST.
(The same errors would show up also under Unix(tm).) They are:

- MOSHE.UUE ARC complained about CRC error at UUENCODE.TTP!!
- KRABAT11.UUE ARC stated that OPENINGS.ARC was truncated. DeARCing
OPENINGS.ARC mentioned that WOLGA.OPN was truncated.
- STUUCP.UUE ARC complained about CRC error at zztime.h

Could someone send me, or tell me where, the missing files? Have others
successfully downloaded one of these files? It would be nice that all
programs at ATARINET (and the other BITNET servers) would be *all* downloadable!

Send anything directly to me; I don't have access to the newsgroups.

Thanks again to the net!!

>'save' function if you send me $20 bucks.

This note prompts me to write a couple of comments. Please followup to
comp.sys.misc only -- I'm sure the folks in the other comp... groups are just
as tired of this discussion as us in comp.sys.mac.

I don't see the problem with marketing a shareware wordprocessor that doesn't
have the "Save" feature. It's a free market and people can offer whatever
they like for whatever price they like. If you don't like a particular product
offering, send a letter to the seller, saying what you think.

For example, I have sent several letters to Electronic Arts about their
Mac-crippling copy-protection scheme. The last letter I sent them explains
that I recently bought Studio Session (from a competitor) rather than their
Delux Music Construction Set because of their refusal to remove their
incompatibility-causing copy-protection. This feedback method is called
"Voting with your wallet", and is very effective.

A lot of postings in this discussion seem to be trying to pin particular
definitions on the terms "Shareware", "Freeware", "Demoware", and others,
yet I've never seen commonly-accepted definitions for these words. How
do you feel about these:

"DemoWare" - a demonstration version of a program. This version lacks
certain important features (e.g., "Save") or it has a limited
life (e.g., after June, 1988 it fails to work anymore).
If you send the money in, you get a complete version of the
program.

"ShareWare" - a complete version of a program. No missing features,
no booby-traps. If you send in the money, you get recorded
as a licensed user. This license may provide you with extra
stuff (e.g., updates or manuals) but it doesn't give you
anything that makes your initial copy of the program work
any better.

"ThugWare" - a program that deliberately attempts to penalize the user
for using the program, in a mistaken attempt to punish
software pirates. E.g., a program that erases your
disk and prints "The wages of sin is death".

It's my opinion that anyone who builds such software is
asking for a punitive-damages suit.

"Free" - a program that you can copy and use without sending anyone
any money. This category includes both copyrighted-but-free
programs and public-domain programs. A Free program never
asks for money.

"Public Domain" - Let's use this term with its legally-correct meaning:
public intellectual property. In the USA, anyone can do
anything they want to a public domain program.

>...I will be registering my copy of ZCOMM shortly....
It looks like this user is another of the crowds of "the check's in the mail"
shareware users. No wonder nobody is making money on shareware.

Shareware would be a great idea in the best of all possible worlds, but the
concept has been so degraded by every weekend programmer who thinks he can
get a few bucks for his 2-hour hatchet job and by every toothless legalistic
message that says "send $15 or you'll hate yourself and I'll come after you
with my lawyers" and by all the two-faced users who say "this program is
great, but I just don't have the money right now" that shareware's day has
come and gone. Expect to see nothing but Free, DemoWare, and ThugWare in the
future.

By the way, is anybody paying taxes on their shareware spoils, or is this
all black-market money?

No benefits ?! It's a major nuisance to always think of moving those f&*%ing resource-files around together with the programs. Separate resource files are also a violation of GEM's idea of (well, kind of) 'object oriented-ness'. It's, for instance, not possible to open files of a given type with some (application-) program if the resource file for that program happens to reside in any other but the current directory.

BTW., is anybody of Mark Williams Corp. listening ? I never got an acknowledgement for the MWC customer registration card I sent to Mark Williams.

>
> Oh wait, you mean multi-processing. Well, when UNIX does this, with
>three disparete environments, let me know!
Hmmm, well Sequent does run multiple processes on multiple processors and
unix works fine.

Alliant doesn't seem to have a problem mixing unix up with CE's and IOP's.
I believe the IOPs are 68020's.

CDC 825 (don't know if this environment is still for sale) ran NOS, NOS/VE,
and an unix sys V clone all at once. Note that the processor was switching
instruction sets and memory managment schemes in mid stream. Quite a nice
idea, and it worked. The hardware was great, but the software was
a different matter entirely. I remember one of the engineers looking
at incredously when I asked for wild cards in the SCL for NOS/VE.

The Amy is nice technology for personal computers, but it is
by no means the forfront of technology today.

> and cause media changes every once in a while. I imagine a media change
> on the hard disk wouldn't get in the way much, since it should be fairly
> quick to reload. Do you see any problems with this idea?

Yes: a huge one. When you get media change on a drive, all open files
on that drive are closed & forgotten. No data is flushed, no warnings
are issued... You just get kicked out in the street. Not a fun thing
to have happen at Vblank time.

Having a program which causes media change is another matter. In fact
I have one, and use it when I pop a floppy, modify that floppy on another
machine, and re-insert it in the original. (Without such a program,
the state would go from not-changed to (pop disk) maybe-changed to
(re-insert, check serial number) not-changed.

But it requires user intervention, and the better solution is just
to fix the damn bug in the first place.

> Where can we get C sources for gemdo[s] in North America. How much
> is 68.00 Deutsche Mark?

If Atari Germany sold the source to Gemdos, it overstepped the bounds
of its authority. I believe that we do not have the right to distribute
source code to Gemdos, which is, originally, a DRI product.

You can't get it (legally) in North America.

I urge you not to try, because it will create such chaos. Atari cannot
be expected to support an OS if everybody with a C compiler can create
his own version. Please be patient: I'm not kidding when I say the
new GEMDOS will be out soon. (By "soon" I don't mean "next week."
I mean "sooner than you could get the source, figure it out, make any
useful changes, and debug them to the point that you would trust your
hard disk's file structure to it.")

> we are getting a ^C or a Pterm().
> --j.a.tainter

You're getting a Pterm if you call Pterm, and you're getting ^C if you don't. If you know you're calling Pterm, then call your clean-up routine on your own and un-install it before you terminate.

Also un-install your terminate vector before you Pexec: you can tell what the result of the Pexec was by the return code: -32L means the child terminated with ^C. Any other LONG negative value means the Pexec failed, and any LONG positive value (i.e. (x & 0xffff0000) == 0) means it called Pterm(x).

Please don't shoot words like "worthless" around unqualified.

in article <4805@ihlpg.ATT.COM>, tainter@ihlpg.ATT.COM (Tainter) says:
>> [...] why not release the bug fixes now?
>> /Leonard

> [...] Every month or so
> you get to buy a new version of the ROMs.
> --j.a.tainter

That is exactly what will NOT happen. If I had just "released the bug fixes" when I thought they were pretty much done, you would all be complaining that there were still bugs (and some new ones). That's what internal test and pre-release beta test are for. If you want to see what happens when you "just release" things, look at comp.sources.bugs some day.

Atari is a multinational corporation, and has to support what it releases. Maybe you're not satisfied with the level of support, but I think it's ludicrous for you to ask that it be LOWERED.

1813. Re: Memory Chips

Newsgroup: comp.sys.atari.st
Date: 1988-02-17 00:04:09 UTC
From: craig@unicus.UUCP
Message-ID: <2224@unicus.UUCP>
Source record: 254363
Cross-posted to: comp.sys.amiga,comp.sys.atari.st

Well, up here in the Great White North, where we don't have to protect
the mighty Micron from going out of business...

I think I could find something to beat $4 US. Last I looked, I (Logicraft)
could sell 256K 150 ns DRAMS for $4.50 CDN or so, that is, at the time about
$3.30 US. Of course, the US dollar has dropped a little since then,
and I think chip prices moved up slightly, but I still think I could
sell 256K 150ns for less than $3.50 US, or about $4.25 CDN.
120ns chips were a little more expensive, $5 CDN and 100ns were much
worse, about $10 CDN.

Of course, these are all still Japanese chips, but I don't know how
much US Customs cares about high-tech pass-throughs.

Just give me the price to beat, and I'll see what I can do.

In article <1924@optilink.UUCP> cramer@optilink.UUCP (Clayton Cramer) writes:
>My two cents about shareware: I originally distributed my Epson MX-80
>to PostScript translator (in a very early form) as shareware. Total
>amount received: $0.

So why was it that you wrote the thing? For your own benefit, right?
Total extra effort on your part, 0; total monetary benefit to you, 0.
Sounds about right to me. Had you gone and added all of the stuff that
people asked for and still not gotten any contributions, then you
would have something to complain about.

I use one piece of shareware, Handshake. I've made my contribution,
but it is a commercial quality program that works amazingly well, and
the author has put in many enhancements for his users, even some that
he felt didn't belong there. But users wanted them and they got them.

If you had to fix your program up to sell it commercially, then it
really wasn't worth anything in the first place, was it?

>Clayton E. Cramer

1815. curses.mwc part2/2

Newsgroup: comp.sys.atari.st
Date: 1988-02-17 01:40:35 UTC
From: cjp@stag.UUCP
Message-ID: <340@stag.UUCP>
Source record: 254365

```
CURSES2.SRC CJPurcell 15Feb'88
some times: como!cpurcell@eta
other times: cjp@stag.uucp

This document and the source code is shar'ed (skip down about 50 lines to
find it) and consists of:

curses.man both useful and necessary
curses.c curses source, as slightly modified for use with MWC
curses.h include file, for inclusion in your various sources
twinkle.c demonstration of both practice and performance

Re:This version: The document was found stored in our club bbs-essentially
in a useless form. Somehow the doc/manual was stuffed with large strings of
overbar characters(i.e. 0x00ff bytes) and the tab format utilized in the code
was (is) equally strange. Who knows how many twisted(blue?) transformations
were required in order to arrive at my house. TINYTOOL.ACC to the rescue!
Poke by poke! But, I wanted to learn about curses AND I wanted curses on
the ATARI-ST here in America.

MWC conversion notes are as located in the source. The only important note
is to avoid the use of the unportable PORTAB.H (-) . The grubby note is
that many long lines in the source are(were) truncated during the compile
phase, as well as by the editors,so SHOW.PRG to the rescue once, again,
so as to establish the intent of the original program. Possibly the source
was "beautified" before publication. It turned out to be a poor choice.

The program TWINKLE.TOS was prepared by the author to prove this version
of curses. I get the same picture with MWC as was provided originally. No
other testing has been performed. I still don't know much about curses.
**********************************************************CJPurcell

The following was garnered from a previous post by Mr. Turner...
>
>This is an emulation of the curses library in UNIX. It is a series of
>library routines which allows the user to control cursor positioning
>and output of characters in one or more 'windows'. A curses window is
>defined as a rectangular area of the screen whose size is as small as 1
>char or as large as the whole screen.
>
>Despite what Rene says in his comments, I have not been able to get
>this to work under anything but Alcyon C. MWC compiles but will not
>execute properly and Megamax aborts with compile errors. I'm afraid
>that I am too far behind as it is and can not spend any more time
>trying to port this. Perhaps some kind soul......
```

seems to work fine for MWC now...

>There is one change that needs to made for this to work under Alcyon C,
>the size of the stack in gemstart.s must be increased from 500 to
>10000. The place to do this is fairly easy to find since it is
>commented in the sources. <<In MWC I set _stksize = 10280; >>

```

X
X
XNAME
X
X curses - screen functions with "optimal" cursor motion
X
X
XDESCRIPTION
X
X The functions in the curses-package give you an implementation of the
XUN*X-curses package for the Atari ST series computer. It allows you to do
Xterminal-oriented graphics of a crude nature. An image is kept of what the
Xcurrent screen looks like, while the user creates a new image. Refresh()
Xmust be called to make the current screen look like the one the user has
Xprepared. Initscr() must be called to initialize the package and endwin()
Xto clean up before exiting.
X
XSEE ALSO

```
XAUTHORS
X
X UN*X-curses : Ken Arnold.
X Atari-curses : Rene van 't Veen.
X
XFUNCTIONS
X
X addch(c) add a character to stdscr
X addstr(s) add a string to stdscr
X box(win,v,h) draw a box around a window
X crmode() set cbreak mode
X clear() clear stdscr
X clearok(scr,f) set clear flag for scr
X cltobot() clear to bottom on stdscr
X clrtoeol() clear to end of line on stdscr
X delch() delete a character
X deleteln() delete a line
X delwin(w) delete window w
X echo() set echo mode
X endwin() end window mode
X erase() erase stdscr
X getch() get a char through stdscr
X getstr() get a string through stdscr
X getyx(w,y,x) get current coordinates
X inch() get char at current coordinates
X initscr() initialize curses
X insch() insert a character
X insertln() insert a line
X leaveok(w,f) set leave flag for window w
X longname(termbuf, name) get a long terminal name
X move(y,x) move to (y,x) on stdscr
X mvcur(ly,lx,ny,nx) actually move the cursor
X newwin(lines,cols,begin_y,begin_x) create a window
X nl() set newline mapping on
X nocrmode() unset cbreak mode
X noecho() unset echo mode
X nonl() set newline mapping off
X noraw() unset raw mode
X overlay(win1,win2) overlay win1 on win2
X overwrite(win1,win2) overwrite win1 on win2
X raw() set raw mode
X refresh() make terminal look like stdscr
X scroll(win) scroll win one line up
X scrollok(w,f) set scroll flag for window win
X standend() leave standout mode
X standout() enter standout mode
X subwin(win,lines,cols,begin_y,begin_x) create a sub window
X touchwin(win) change everything on win
X waddch(win,c) add char to win
X waddstr(win,s) add string to win
```

```
X wclear(w) clear w
X wclrtobot(w) clear w to bottom of w
X wclrtoeol(w) clear w to end of line
X wdelch(w) delete character from w
X wdeleteln(w) delete line from w
X werase(w) erase w
X wgetch(w) get a character through w
X wgetstr(w,s) get a string through w
X winch(w) get char at current (y,x) of w
X winsch(w,c) insert a char on w
X winsertln(w) insert a line on w
X wmove(w,y,x) set current coordinates of w
X wrefresh(w) make terminal look like w
X wstandend(w) leave standout mode for w
X wstandout(w) enter standout mode for w
X

+----------

I agree.

I used to work for a company in Southern California whose policy it was that if a customer was in any way not satisfied with the product, the could return it, if they keep the receipt, for a full refund. We would then test it, make sure all of the docs were there, then re shrinkwrap the product and place it back on the shelves.

MOST of the time we never had a problem with this. Most customers were able to realize that the policy was set there for those that REALLY did not like product, or felt that they had not gotten their money's worth, and did not abuse it. There were, however, a few people that would buy at one of our stores, and return at a different one. Every return is fully documented, whether or not we give cash or store credit back, and sometimes, if the sales person, or the manager thinks that the return is not quite on the up and up, he or she will phone other area stores and inform them that we have had a return, and they may want to be on the lookout for a series of them by the same person/people.

The worst case of this abuse was a customer that purchased the FULL doctor's office manager, and several other IBM brand software packages, at different times, then proceeeded to return them within two days. The first time we said ok, the second we grimaced, and the third we informed that they were no longer allowed to return a product unless it was defective, and we would be happy to test it on our machines before they left the store so that we would know right off if it was defective or not.

Overall, this policy, of being able to reshrink has a great number of ad-vantages, but it is too bad that some feel that this is an opportunity to "rip off" software manufacturers, authors, and dealers.

Scott

The computer store I have worked at also did something similar to this. We would make a copy of software to demonstrate and then reshrink-wrap it. The reason is that customer's keep wanting two otherwise mutually exclusive things: 1) They want to see something demonstrated before they buy it and 2) they want a shrink-wrap fresh copy of software to buy. We couldn't afford to keep an original of every program strictly for demonstration purposes. Since we had a very liberal exchange policy on defective merchandise, we felt that the very slight risk of damaging the original during copying was worth it. We would also test the original after copying to make sure it still worked before shrink-wrapping. However, any of the copies made were strictly for in-store demo, they never left the premises and no copies were distributed.

> reviewer you can find, have heard of, or is even rumoured to exist. Upload it
> to GENIE, COMPUSERVE, etc. Call into bulletin boards across the country
> and upload it. Post it to usenet. When people make queries about applications

One note: Do NOT under any circumstance upload it to Compu$pend - I have heard
that they have this weird idea that they hold the copywrite on ALL material
that comes from their system, including things which users have uploaded! I
have heard that they have hassled some BBS's which were carring programs that
a user would download from CI$ & then upload to the BBS in question. If you
want to avoid the hassle, avoid using Compu$pend.

>The results were NULL.

Well, what did you expect? What with qmodem, procomm, and pibterm, you've got some excellent competition. You, like the other person who was disappointed by the lack of "sales" of their terminal emulator (no matter how nifty), were targetting a oversaturated market. How about writing a program that no-one has even thought about writing?

Shareware is just another marketing scheme, not a miracle worker.

>
>I won't mention any names here, but I think it is wrong to do the above.

Please DO mention names! This sort of thing could cause incredible hassles
for the eventual purchaser of such a re-shrinkwrapped package.

Consider this scenario:

A software company finally gets fed up with piracy and decides to go after
pirates. They try to collect as many illegal copies of their software as they
can, offering "amnesty" to those who had them, and sue the registered owners
for each serial number they find in their collection.

The customers of the store you are referring to have no idea that there are
illegitimate copies of software with their serial numbers floating around out
there, and suddenly they have a lawsuit sprung on them!

Don't say that won't happen, I have heard of two instances when it has!

So DO mention names, so people will know where NOT to buy software.

Message-ID: <341@stag.UUCP>
Source record: 254379

In article <33697CEN@PSUVM> CEN@PSUVM.BITNET writes:
>Could some kind soul please explain exactly what is in the Curses package?

Curses is a package that provides a standard set of i/o control functions. It includes standard screen postitioning calls (simple things like moving to a location on as screen as well as complex things like managing multiple windows) and standard input char/line options. The real advantage to using Curses is that the calls are pretty much standard. If you write a program that uses Curses for screen management on one Unix system, then you can be pretty sure that it will run on most other Unix boxes (and equally importantly on pretty much any type of terminal that is attached to the unix systems since curses will look at the terminals TERMCAP/TERMINFO file for you and handle all the messy logic.

If you are writing a program that you intend only for the ST, then I wouldn't recommend using curses. Just use the vt52 esc codes and throw in all the graphics you care to use. If you plan on porting the program over to an IBM PC or Amiga or Unix, then curses comes in handy.

>an hour to write MacDoodle? More clearly stated, you should probably said
>"I got some money for 'MacDoodle 1.3'" because the word "made" implies that
>more money came out of the result than went in.

What you are forgetting is that a lot of us write software for the fun of it (i.e. to learn something or because we need a tool for a very specific need). The cost of developing it is paid back either in our 'learning' or in the time the tool saves us (else why would we write the tool?) In these cases, putting the program out as shareware is simply gravy (and further incentive to put out more useful tools). One bad thing about shareware that I have seen in the Mac world is that people seem to be throwing a shareware label on almost every piddly little program that they can think of. When I see a shareware notice on a simple program that took the author only an hour or two to write, then I think the shareware concept is being stretched a bit.

I am sure the MacDoodle author got a fair amount of satisfaction out of developing MacDoodle and a lot a satisfaction out of the knowledge that there were several other people out there that liked his program. You shouldn't ever write a program and expect everyone to like it (although it would be nice). I have had a bit better luck with HDSCAN on the ST, possibly since I also offer a more advanced version for sale on the ST. The shareware version allows people to decide whether they really even need anything better (most may not actually need the extra features). The Unix version has no such teaser, so I doubt it will bring in anything...

-Todd Burkey
trb@stag.UUCP

P.S. Chuck, I was really impressed with how fast HDSCAN ran on the Sun 4 that we had in for evaluation several weeks ago...It scanned 100+ MB of files (the full file system) in under 10 seconds. That seemed a lot faster than when I run it on our Sun 3/60's (which it looks like we will be getting more of anyway...the 4 was too expensive). It also proved invaluable, since the evaluation unit showed up without any documentation or information as to where anything was on the system so I had to do a lot of perusing to figure out what we did and didn't have on the system...

What is ludicrous is that in 3 YEARS these things have not been fixed.
Why should it take 3 years to fix what you have said was originally
written in one month?

Leaving alone the 40 folder bug. Why have these things not been fixed
in 3 YEARS.

Why can you write to a file that is opened for read only?
Why is the fat search so slow? It is obscene that it takes so long
to open a file or check disk space.
Why does tos sometimes say a file is not there when it is, if the
file has been added to a disk after some subdirectories have been
added?

The new tos roms have character ouput sped up and the RS232 handler
rewritten. These were the LEAST obnoxious of the bugs in tos!

Perhaps when Atari supports their machines professionally, professionals
will buy their machines. Until then, my company is dropping its support
for the ST.

You've heard wrong.

Compuserve claims a compilation copyright, i.e., a copyright on their
entire collection of material as a whole. They do not attempt to
claim copyright ownership of individual items their customers place on
the service. This is easily verified by reviewing Compuserve's online
copyright documentation.

They have, on occasion, contacted individuals offering on for-pay
BBS's collections of files downloaded from Compuserve. On those
occasions the individual was asked to remove files downloaded, since
that specific activity is prohibited by the contract a user agrees to
when signing up with Compuserve. On at least one occasion, such an
incident was reported in the press in a distorted form.

I'm not totally without an interest in this subject: I manage one of
the Compuserve Forums. However, I'm speaking for myself, not as a
representative of any other person or entity, especially Compuerve or
my employer.

Source record: 254386

in article <449@dukempd.UUCP>, gpm@dukempd.UUCP (Guy Metcalfe) says:

> Question: is there a 100 file limit on root directories?

Yes. There is a hard limit set at format time: the root directory size
of any GEMDOS (and MS-DOS) logical device is constant.

Subdirectories don't have this problem because they are allocated as
files; when there's no more room, another cluster is allocated to the
end.

What *is* unfortunate is that subdirectories never shrink. If you
create 1024 files in a subdirectory, then erase them all, you'll have
an "empty" subdirectory which takes up 32 clusters on your disk.
Removing the subdirectory (rmdir) reclaims that space.

>One note: Do NOT under any circumstance upload it to Compu$pend - I have heard
>that they have this weird idea that they hold the copywrite on ALL material
>that comes from their system, including things which users have uploaded!

I remember when this was being discussed last year, and I think you are overreacting. Compuserve claims what is known as a "compilation copyright". They don't copyright any individual item, but they copyright the collection as a whole. This is analogous to an anthology of short stories that have been previously published separately -- the stories are still copyright to the original publishers, but no one else can publish that particular collection of stories. In general, I think this also covers very similar collections (i.e. you wouldn't be able to get around the copyright by making a new collection that has all but one of the original stories). So, what Compuserve doesn't allow is for someone else to download a large portion of their library and then make this available to others. For example, a user group can't just download the entire Compuserve library and make enough copies for all the members. It's easy to see why they would be against this: a significant portion of Compuserve's revenue comes from people being online to download files; if one person does the downloading and then gives away copies for the price of the media then Compuserve is losing revenue.

If Compuserve thinks they hold the copyright on any contributed material they are wrong. As soon as you write something you hold the copyright on it, until you do something that causes you to lose it (such as selling the copyright to a publisher, or placing it in the public domain). If you are smart enough to put an explicit copyright notice in the text then it would be difficult for anyone else to succeed in claiming the copyright.

[P.S. Why do so many people have much trouble spelling copyright? The definition of "copyright" is "the right to copy", so why do people think that the spelling changes when you combine it into one word? One day one of you is going to get screwed when a misspelled copyright notice fails to hold up in court (actually, I think it pretty unlikely that a court would be so picky).]

Source record: 254389

>I see no advantage [in including RSC files]
first, you will not have to move around two files. Second, you can execute the program from anywhere - try using an installed application if your .prg and .rsc are on another partition on the hard disk from the application (There is a way of getting around this). RSC files take more space and load time than when they are merged. Some programs maintain two large .rsc files, one for monochrome, one for color, when only a few parts have to be duplicated.

>I would be interested in others who use MT C Shell...
I use it all the time. I am using it now. Since I have programs that run
in the background to do the file transfers and dialing (for PC Pursuit),
and they don't kill the foreground, I start them and do other things on
my ST while waiting. Very few programs crash, and I have found alternatives
that don't. I only have a meg (and a LOT of auto folder stuff), so I can't
run a lot of stuff in the background. I do have things that will allow me
to break out of a program from anywhere (like control-c, but without waiting).
I use Micro C Shell when I am not using MT.

1840. Re: file limits of root directories

From: Thomas_E_Zerucha@cup.portal.com
Message-ID: <3292@cup.portal.com>
Source record: 254391

This is also a limit in MSDOS. The root directory's size is specified in the boot sector at format time. Floppies normally default to 128, Hard disks to 256, but if you edit the boot sector, you can make it any number you want (@16 entries per 512 bytes sector).

1841. Re: A decent disk cache...

I don't know of any that just cache the FATS completely and the rest dynamically, but I have a short assembly program that increases the number of FAT buffers in GEMDOS - but I don't use it since Beckemeyer's Hard Disk Accelerator seems to do a good job all around. Optimizing the disk helps too.

1842. Re: Atari 68030 computer?

Newsgroup: comp.sys.atari.st
Date: 1988-02-18 02:11:58 UTC
From: good@atari.UUCP
Message-ID: <983@atari.UUCP>
Source record: 254393

First I should introduce myself. I have recently joined Atari's engineering group with responsibility for the coordination of product development, both hardware and software. So now you've all got someone new to singe! One of the things I will be trying to implement is a more structured and timely approach to the release of information regarding the status of new products, their specifications, capabilities etc, as well as trying to bring more focus into the channels through which such information is disseminated.

For the Atari 68030 UNIX (tm AT&T etc etc) system, the story is that the ubit will be previewed at Hannover to a very select group of invitees. I have perhaps a more cautious view towards product announcements and release, and prefer to wait until a product is in a known and marketable state before making definitive statements. Others in this industry do not necessarily share my viewpoint!

The 68030 will be a full V.3.1 SVID-compatible unit, and it is my hope that we will be able to fight off the inevitable clamoring for early units until such time as the entire product has gone through all the test cycles that such a product needs to be exposed to before it is ready for mass release. By 'entire product' I mean the real system, including options and supporting software and applications, and not just a very good box which comes up with a prompt. Right now our prototype design looks good and is happily running a lot of UNIX code, but there is still work to be done to make it a complete product, including various neat and special interfaces.

By the same token, I do not like to see software put out for general arrow-shooting until our own quivers, and those of our closest trusted associates, have been emptied. And then it will be released for a reasonable Beta test period before being made generally available. Many of us here do read the input for enhancements, fixes etc, on this net, Bix, Genie and Compuserve. Much of that input has been acted upon for the upcoming TOS release for ST & Mega. Some of you will doubtless be disappointed that your own pet wishes have not all be incorporated; many of you will be glad to see that we have taken notice.

It is very easy to be forced into premature releases due to public pressure. And very dangerous. I hope we at Atari, and you the valued customers, can work together to provide a better product for all.

Roy J. Good
Product Development, Atari Corporation

Views expressed are my own. Atari may agree or disagree; they have the right.

1848. Sound, Speech-recognition and Magic Sac

Newsgroup: comp.sys.atari.st
Date: 1988-02-18 10:14:00 UTC
From: VDGRIEND@HEIIPO5.BITNET
Message-ID: <8802181238.AA18225@ucbvax.Berkeley.EDU>
Source record: 254399

Dear brothers and sisters on the net,

I have some remarks and some questions and would like to receive reactions.

1. Some time ago (digest 87/420?) I asked for help to do A-D and D-A
(the latter also by the monitor speaker). I got no reaction.
But on the HCC-dagen (the biggest comp.hobbyist-fair here in Holland)
I bought the ST Soundtrack. It does 8-bit A-D and D-A, also with the
monitor as an output to about 50 KSamples/second (On the monitor 31
I think) and has a lot of nice features. It sells for about Dfl. 165.
Hardware+Software. You can connect it to your audio-equipment.
Hardware is a cartridge for the ROM-port. If you would like more INFO,
please let me know.

2. Is somebody working on speech-recognition by the ST?
I bought the Micromint Lis'ner 1000 and would like to use it on the
ROM-port. I'm convinced it is possible, not all the signals needed are
available on that port but they are in the ST. Has somebody done it
already? If so, please tell me. If you did interface another Apple][
bus card to the ST, I'm interested to hear too!

3. To David Small c.s. : It must be possible to do Mac to ST conversion
on the Mac only, is that right? Because the drive is under software
control it could be possible to read and write ST-compatible disks,
provided the neccesary software ofcourse. Or am I terribly wrong?

4. I have a Protek acoustic modem 1200/75 baud, but did not succeed in
working with bulletin-boards here in Holland. They do not seem to
recognize the PROTEK. Does somebody know why and how to fix it?
(It does work with VIDITEL compatible services).

Thank you for reading. Please react if you can offer help !

A colleague tells me he has recently acquired a 1040 STF with the new OS roms and finds that he can no longer remove John Franco's ETRNL2 ram disk by doing a reset with CAPS LOCK held down.

Any ideas why that might be? Any chance of a fix ... John?

From: franco@iuvax.cs.indiana.edu
Message-ID: <36500031@iuvax>
Source record: 254302

I have successfully fixed my Chinese mouse so that it performs like a Japanese one. Recall that someone had said that his mouse pointer did not accurately reflect mouse position changes (on his Chinese mouse). I had a similar problem which I traced to the idle roller assembly being loose. Unfortunately, it is loose by design. However, by stuffing tissue paper into the spaces between the roller arm and the roller housing I was able to get correct roller action. My mouse is now even smoother than my old Japanese one.

Alternate solution: buy a mouse from another vendor...I don't think Atari has figured out how to make these things yet.

I was watching the Winter Olympics the other night, and saw a teevee commericla for the 520 ST (nice and slick, too). Question is, is this a locally-sponsored ad, or (gasp!) is the rest of the continental United States getting the commercial?

Also, how many other Atarians in netland have seen Atari commercials with somewhat recurring frequency? Considering that one of Atari's biggest problems (in my book) is lack of mass-advertising, this might be a good sign...

1856. GEMDOS bug (attn -- Alex)

Newsgroup: comp.sys.atari.st
Date: 1988-02-18 18:04:00 UTC
From: JEMCCABE@MTUS5.BITNET
Message-ID: <8802190133.AA02942@ucbvax.Berkeley.EDU>
Source record: 254307

Date: 18 February 1988, 12:35:09 EST
From: Jim McCabe JEMCCABE at MTUS5
To: INFO-ATARI16 at SCORE.STANFORD.EDU
Subject: GEMDOS bug (attn -- Alex)

[]

I have found an annoying bug in GEMDOS, and it occurs so frequently
that I'm sure someone out there must know how to avoid it.

In a disk-storage-intensive program I'm working on, it becomes advantageous
to be able to swap disks after loading the program. (For example, one
might load the program, then insert a data disk...) I've noticed that
GEMDOS is consistantly unable to read in the new directory tree from the
new disk. After swapping disks, my application has no trouble locating
files in the root directory, but all attempts to open files that are
in a subdirectory of the new disk fail with an error -33 (file not
found).

I asked this question before, back in October '87. Mike Fischer
(fischer@yale.arpa) was the only one to respond, and his answer was:

> One
> fix is to use Fsfirst with a path in the root directory to force
> GEMDOS to access the disk after the swap. Then you should be able
> to follow that by an Fopen for the file you really wanted. Note
> however that if you are not specifying the complete pathname (with
> a "^" immediately after the ":"), then you are asking for a file
> relative to the current working directory, which hasn't been resent.
> If this is your problem, then you also need to set the working
> directory after the disk swap.

I tried his advice, and it doesn't work (at least not on _my_ ST).
Here's the order I perform his fix: (psuedocode)

```
dsetdrv(0); { Set current drive to drive A }
dsetpath('A:^'); { Current working directory = "A:^" }
fsfirst('A:^*.*', 0); { Read first file from root directory }
fopen('A:^MESSAGES.BBS^BOARD30.MSG'); { I know the fopen syntax is
wrong here, but ignore that }
```

And it still can't find the file! Can anyone help me, please?!?!?

Thanks!

1857. Re: Bad (but ANY) placing of Atari ST binaries

Newsgroup: comp.sys.atari.st
Date: 1988-02-18 18:42:18 UTC
From: jbww@eagle.ukc.ac.uk
Message-ID: <4460@eagle.ukc.ac.uk>
Source record: 254308

Surely ANY posting of binaries and source is better than none.

During most months of late 1986, early 1987, I captured about 1 disc full per month from the net. (Four during Jan 1987!)

I doubt if I have had 2 discs full in the last six months.

I don't believe this is because people are not writing things; I have managed to get quite a bit by going (literally) disc in hand, to the right people, and have heard of quite a few things that were on their way to ST source/binaries, that have never appeared.

Yes, the sources and binary groups are the right place, but I think the time has now come to post here, rather than nowhere.

Things that I have heard of, and would like to see :
(But please don't mail them to me without checking: we have limits)

Molecule; Aim V2 + new data files; 1stLatex V2;
regular updates of Uniterm (have 2.0a)
StCad; Icon V2 ; Levee ; Colour flipping tools (and demos)
Uniterm2 docs (Tex or otherwise); blitter docs

Are there any upgrades to the originals of the following :

Starchart; DviSt;

Something that I have just got, and can recommend : 1stw2PS

File transfer is probably easy in the States, not so good this side of the Atlantic, person to person mail across the atlantic seems a waste if many people want it, so : PLEASE LET US HAVE PROGRAMS, NOT JUST TALK !

Fat chance of that happening, over the period of the last two years Atari has simply refused to make GDOS available as a seperate product, delibertley crippling the ST as a result. As far as I know the only way to get a copy without buying a software package is to buy an Atari laser printer :-/.

>> /Leonard
>
>--j.a.tainter

I replied to Allan's message about the bug fixes, suggesting that the patches be posted here (since he expects them to be only 32K). No response. So now I'm posting my comments...

I am a "registered developer" (ie, I bought the developer's kit) even though I don't produce any products, but I haven't heard anything that suggests I'll get a set of ROMs, even if I do have to buy them. I didn't receive an offer to acquire or purchase GDOS either, even though it exists (it comes with certain software packages).

You know, the Atari ST series of machines are quite amazing devices...Too bad Atari doesn't seem to see it that way. They keep leaving out key ingredients that would give the machines a decent chance of taking off... Like GDOS...and a write signal on the cartridge port...and support...

1861. Delivery dates

```
Since I have not seen this message in any of the ATARI-16 digests
I post this again:

New release 1stw2ps Version 3.1 4 February 1988
================================================

1stw2ps is a program that makes a postscript file from a 1stWord
or WordPlus file. The printout you will get looks much better than
that from any 24-pin, dot-matrix printer.

Spaces are adjusted so that each space occupies the same length on
a line.

New: Several special characters are supported:
-- Output to RS-232 or Centronics.
-- Special header fontstyles.
-- Date and time inclusion.
-- Most (all?) bugs are fixed. I just forgot them.

Contents of (uue) archive :

Name Length Storage SF Size now Date Time CRC
============ ======== ======== ==== ======== ========= ====== ====
1STW2PS.HEX 1554 Crunched 68% 501 4 Feb 88 11:23p 03ED
1STW2PS.INI 7264 Crunched 47% 3885 4 Feb 88 11:03p E0FB
1STW2PS.MAN 5108 Crunched 43% 2918 4 Feb 88 11:20p 4B17
1STW2PS.PRG 59996 Crunched 36% 38590 4 Feb 88 11:02p 7806
1STW2PS.RSC 7986 Crunched 50% 4029 4 Feb 88 11:30p F85F
==== ======== ==== ========
Total 5 81908 40% 49923

1STW2PS.HEX is a hexidecimal file for INSTALL.PRG which shows the
characters available in 1stw2ps.
1STW2PS.INI is the laser printer initialisation file.
1STW2PS.MAN is the manual.

I am sending a copy to the file-server at Houston (UH-INFO@UHUPVM1). If
somebody out there will be so kind as to post it to atari16.sources or
whatever it is called, I'll appreciate it.

Any remarks, suggestions or just a "keep up the good work" are welcome.

> They have, on occasion, contacted individuals offering on for-pay
>BBS's collections of files downloaded from Compuserve. On those
>occasions the individual was asked to remove files downloaded, since
>that specific activity is prohibited by the contract a user agrees to
>when signing up with Compuserve.

As I remember it, the CompuServe contract says that since stuff on
CompuServe belongs to others, one may not download it for commercial
purposes. The emphasis is on protecting the rights of the owner of the
files which, as Bob Peterson says in his article, is not CompuServe.
This implies that so long as the owner of the downloaded files doesn't
object, one can do anything one wants with the downloaded software.

There is simply no merit in the claim that CompuServe can get a
compilation copyright for material that is already copyrighted without
getting explicit permission from each copyright holder. It is
illegal to create a compilation of copyrighted material for
commercial purposes without explicit permission from the copyright
holder of each item included in the compilation.

CompuServe is on record as claiming that if you download software from
its forums and give it away to others, you are stealing somebody else's
work. Since essentially all downloadable software is shareware or
public domain, one can see that this is an absurd and self-serving
claim made solely to fool the public.

I guess I should clarify that....

Judging from sales, I don't think all that many people would care if
I dropped FoReM ST, but...

What I am not doing is any ST specific development. I had plans for
a multi-user bbs system based on the ST, but there is no reason to
do so.

FoReM ST will stay consistant with the single user IBM PC version as
it is source code compatible for both the main bbs and the FoReM Net
network mail system. When the multi-user 286/386 version comes
out later this year there will be no effort to have it run on the
ST. Too few sales and too much piracy.

Well, just to back this claim up, the story continues...

Exactly 24 hours after I posted my first article about Lyco, the
friend of mine that originally bought his though Lyco called me
up: it seems that his 1040 fryed. Not just your standard, made-in-america
turn in on and it doesn't work kinda deal...I'm talking about:

** FIZZZZZZZZZZZZZ---TTTTTT!!! **

accompanied by smoke and sparks. (I have only seen one other machine
do this: an IBM Portable PC that had the wrong monitor plugged into it.)

So, he opens it up: sure enough the power supply blew. He told me after
the fact that it had been running kinda hot ever since he bought it,
and twice it rebooted for no reason. He bought a new power supply ($45)
and now everything is fine...

...if he has the old one I'll have him look for the Atari Q/C "REJECT"
stickers.

>lots of other fun goodies.
Does it work with GEM? Apparently so, but I had understood from
several people that the GEMDOS would not tollerate any type of speed
increase, even just putting in a 68010, which gives an effective 10Mhz
68k speed. I had also read about a board to put in a 68020 and 68881 running
at various speeds, but they said that too would not work with GEMDOS.
I had been waiting for the release of MINIX/ST to get one of these, but
if it will work now, great!!

>I have a friend who has paid the $200 for a beta board and should get it
>"Real Soon Now."
Could you _please_ give the address if it satisifies the stuff
up above? I imagine alot of people will be interested if it does work
with GEMDOS.

This isn't entirely true. An exception can also produce a Pterm. So
an exception would look like a ^C, based on the above test. The only
way around this is to install your own exception handlers, which isn't
too clean either, if you ask me (but who did, right?).

You have heard wrong. CompuServe holds a copyright on the collection,
not on individual programs. This means you can't download the whole
library and advertise as an alternative to CompuServe, but there's
they place no restriction on redistributing individual programs.

Get the facts before spreading this kind of message.

Thanks for the report on the 68030. I am wondering if there will be at least a socket for a 68882 (if not the chip - or the 881) or some other support for floating point. In this case I think I prefer to stick with the standard 882 instead of going custom.

Get real. DAs are just bogus fake multitasking. What Multitasking buys you in a robust OS, with some reasonable odds of not crashing, is a "MIX 'N' MATCH" approach, a la carte, versus "It'll do everything you want: err, whay would you want to do *that*?" (aka "Integrated Software Packages").

Ten months ago, as I was saying goodbye to some friends in a Minneapolis C=A dealer's sales room, I overheard a serious-sounding customer off in the far corner, talking to the salesguy: "...don't think I'll *ever* need more than two meg..."

I grin. MT is the same story.

Now, if only C=A had had the sense to lay some *good* "DA"-like code and utils on us, all of which used clipboards, with public availability of the critical sourcecode... Naah, never mind. They should have done that two years ago.

I think the ST's OS can't handle OTHER processors - such as the 68010 and
68020, but it is likely that a faster 68000 would work fine. Which brings
up the question: Does the accelerator board use a 14mhz 68000?

In article <1375@netmbx.UUCP>, hase@netmbx.UUCP (Hartmut Semken) writes:
>
> Hmm, sounds fine but...
> No pricing? Why?
>
The reason is simple, the solution complex. I have to figure out how
many ram disk chips would sell. I have to be accurate as the number is
important to re-coupe developement costs of the custom chip.

About the hard disk accerlerator. I believe an external ram disk is
still the way to go. The accelerator will only help a tight grouping
of disk accessing like compiles and still not as fast as a ram disk.
But for just loading a program, ie emacs, the accelerator will be of no help.
It can't be much help on temporary files (can it?).

Any comments???

The pricing structure will go like this. Estimate total sales
of the chip. Divide by development costs. Sell chips at some price, thus
the first twenty chips will be the same price as all the rest.
My problem is I don't know anything about marketing!

Glen

PS. still some confusion...the ram disk does not increase core. If
you have a 520 and a program needs 1 meg to run the ram disk will not
help (unless you have virtual memory op. system). for those who then
say "Well, what good is it?"- Never mind.

When I asked that the bug fixes be released now - I assumed that the message Mr. Pratt had posted said numerous bugs had been fixed! Isn't the best way to find bugs in software to release it to the public that uses it in ways the developers never dreamed of (if they had, the bug wouldn't be there in the first place).
My original comment was to make bug fixes and the ROMS public domain. They are only ofuse to people who bought ataris, and distribution would be much cheaper and faster. I have eproms I can program - why should I pay $100 for bug fixes in new roms?

1882. UK Server for public domain ST software

Newsgroup: comp.sys.atari.st
Date: 1988-02-19 16:24:17 UTC
From: andrew%MARV@EENG.BRAD.AC.UK
Message-ID: <8802191624.AA10025@marvin.eleceng.bradford.ac.uk>
Source record: 254333

We have just started a server for public domain software for Atari ST's.

The JANET address of the server is

server@uk.ac.bradford.eleceng.marvin

However, the machine the server is running on is fairly new and is not in everybody's address tables yet. If you have trouble, send to

server%MARV@uk.ac.bradford.eleceng

and your message will be forwarded. The first time you mail the server I will register you as a user and send you instructions for requesting software.

The selection of stuff available is a growing fast, but new contributions are welcome :-). If you have problems using the server you can send mail to me (Andrew Minter) at the above address.

Cheers, Andrew

>...Too few sales and too much piracy.

Maybe I'm wrong (why not?), but why are you blaming Atari for piracy
of Forem ST (that's what I read from the above). Piracy is piracy, and to
say "Well, Atari isn't professional enough to stop it, I won't be making
improvements in ST software" strikes me as completely misplaced. I've never
heard of Broderbund dropping their Apple support because of all the piracy
that goes on in that market, for example.

I'm also interested in how many (few?) copies of Forem ST you've sold.
From the ST-BBS-sysops I talk to, they're \/\/ild (hint to someone out there)
about your program, and loyally promote it. Hearing you talk of "low-sales"
is a bit of a surprise.

1884. Compuserve Upload Policy (Was Re: Shareware? Hah!)

Newsgroup: comp.sys.atari.st
Date: 1988-02-19 18:00:31 UTC
From: jwhitnel@csi.UUCP
Message-ID: <1418@csib.csi.UUCP>
Source record: 254335
Cross-posted to: comp.sys.amiga,comp.sys.misc,comp.sys.ibm.pc,comp.sys.mac,comp.sys.atari.st,comp.os.minix,comp.sys.apple

Sorry about crossposting this but this issue keeps coming up and the
original was crossposted as well. Followups to comp.sys.misc.

In article <3343@killer.UUCP> davidg@killer.UUCP (David Guntner) writes:
>One note: Do NOT under any circumstance upload it to Compu$pend - I have heard
>that they have this weird idea that they hold the copywrite on ALL material
>that comes from their system, including things which users have uploaded!

Compuserve does not, repeat NOT, have any copyright (or any other) claims
on any material you upload. The ONLY claim they make is that they have
a copyright on the complete contents of their databases as a unit. I.E.
you can download any subset of the databases you want, but if you download
everything and set up your own network service, they'll get annoyed at
you. But for individual files or groups of files, they cannot and will
not make any copyright claim not permitted by the author. In other words,
if you copyright your software, it is yours and noone can take it away
from you. Anyone who thinks otherwise does not understand the copyright
laws. Next time, David, check out the facts before you post something
you "heard".

Since this issue keeps coming up, I plan to get permission to post an
open letter from Neil Shapiro, sysop of Maug on Compuserve, to the
Apple Programmer's and Developer's Assocation that disccuess this rumor.
My statements are unofficial but are based on Neil's official remarks.
I have no association with Compuserve other then I give them too much
money.

> #define MOUSEY *((WORD *)((char *)aline + -342L))
> #define MOUSESTATE see below
>
> The mouse buttons appear to be (MOUSESTATE & 1) for left and (MOUSESTATE & 2)
> for right. The higher order bits of MOUSESTATE seem to hacve something to
> do with the mouse being moved. If anyone can expand on this information,
> (or make corrections) please do.

The mousex and mousey values above are correct (if a little over-casted).
But the button state can better be read from MOUSE_BT, at offset -596L
from the "aline" base. This variable doesn't have any bits except the
button state bits (bit 0 = button 0, bit 1 = button 1), so there's
nothing else to check.

#define MOUSE_BT *((WORD *)((char *)aline + -596L))

This one is a word, not a byte. Also, you can't cast the constant to a
(char *): it's OK to add a constant to a character pointer, but adding
two pointers is undefined in C. Subtracting two pointers gives the
distance between them, but adding two pointers is illegal. (Naturally,
the Alcyon compiler not only doesn't tell you this is an error, but at
least it generates correct code for what you wanted it to do. The
defines in the quote from dal have been edited by me to reflect this.)

Note that these values are READ ONLY. If you write to them, bad things
will happen and the system will lose track of the mouse state.

All of these "negative line-A variables" were published in the developer
section of CompUServe some time ago. They work for all ROMs.

JEMCCABE@MTUS5.BITNET says:

> I have found an annoying bug in GEMDOS, and it occurs so frequently
> that I'm sure someone out there must know how to avoid it.

> [Description of media-change-not-recognized bug follows.]

We are aware of this problem and are fixing it. The problem happens
mostly when the root directory, fat, etc. of the first disk are so
short that they can all be cached -- There is code to check media-change
to validate a cached buffer, but it seems it isn't being used as it
should.

The bug has to do with the fact that the directory-structure cache didn't
check for media change, but assumed that its internal tree representation
was still correct.

We apologize for the inconvenience. The bug is fixed in the upcoming
new ROMs.

Can anybody that uses the hard disk accelerator (or the author) give us some more information on what it does, especially :

1) Does it speed up reading solely (i.e. is it a 'write through' cache) ?

2) Does it solve the TEDIOUSLY SLOW writing problem on not too empty partitions ?

3) Does it solve the 40 folder bug ? AND/OR

4) Does it work correctly with FOLDRxxx.PRG ?

5) (if the answer to 1 is NO) Does my hard disk file structure survive a power outage occurring between writes (but with a non flushed cache).

Thanks in advance,

- a prospective customer -

I think you may have old information. I'm pretty sure that last year "(c)" was declared invalid. Or, since you are quoting a US form, that maybe it is allowed in the US, but not internationally (since the US never signed the appropriate international copyright treaty, our rules differ). Internationally, only a "c" in a circle (and a pair of parentheses is NOT the same thing as a circle) and/or the word "copyright" can be used, and both of these are also valid in the US.

1892. ICD Driver Bug

Newsgroup: comp.sys.atari.st
Date: 1988-02-19 23:13:48 UTC
From: david@bdt.UUCP
Message-ID: <143@bdt.UUCP>
Source record: 254401

BEWARE!
The ICD Hard Disk Driver has a serious problem. It trashes the
A6 register, which is supposed to be non-volatile.

The error first showed up when we discovered that the Beckemeyer
Development Hard Disk Accelerator used with the ICD drivers causes a
system crash. This error can also affect any program that uses the
"hard-disk" I/O vector at $476 (ram disks, cachers, networks, etc).

The version of ICD Drivers that has this bug is 1.6. Until they
fix it, please DO NOT USE caching, RAM disks, or any other program
that may use the disk I/O vectors. The Supra, Astra, Atari, and BMS
hard disk drivers do not have this bug, and all will probably work
with the ICD host adapter. ICD users: I recommend using one of these
other driver programs until ICD fixes their drivers.

Has anyone ordered the Supra 20Meg harddisk lately? I ordered one a month ago, and have been told since then that it's still out of stock. I call 2 other dealers and got the same story. Some problem with Supra ?!!
Publishing Partner Professinal (V2.0) is supposedly coming out second week of March (that's the latest word I got from SoftLogik early this week). Of course, we can only hope since I was told a month ago that it's coming second week of FEB. Here's a listing of the new features (extracted from Deron's message):

Hyphenation
Spell Checking
Kerning
Taged text
Font in one directory (if you have a file with out a font for it, it can load it if you want to do it's best to display it)
x and y point size changing in 1/50 pt increment from 1/50 pt up to the limits of your printer/free memory (for postscript 18 inches tall, for DM 216-800pts)
Mirror printing
Tiling (printing of HUGE posters) with this one, you can create LETTERS on a poscript printer severall stories tall.
Downloadable fonts for PS
Faster printing on Dot Matrix
Draft/Final modes for each driver selectable from print dialog box
Manual/paper tray feed
grouping
delete multiple pages
current text attribute recall in the dialog boxes, etc.
you can change left/right margin, char line spacing etc by typing in .5 inches or 13 picas etc...
undo
no redraws when changing modes/selecting objects
page numbers from 1 to 254. print the page number in arabic or roman numerals.
multiple documents (ST limit of 6 +moveable toolbox) in a sizable, moveable window.
create/remove directories, disk free space.
search/replace attributes
variable zoom
Greeking (for past displaying very small or large characters by drawing a box or line instead)
Rotate all objects in 1 deg increment
Slant/twist for special effects again on all objects
Delete/insert multiple pages

move a range of pages
Move multiple objects to any page (or just a master page)
turn master pages off on certain pages
import word writter/ 1st word with most attributes
word perfect, Ascii, interpreted Ascii (/b for bold, etc..)
Stripped ascii
pic IMG, Degas Pi/Pc TIFF IFF Neochrome Tiny Spectrum
object GEM, perhaps some CAD type programs.
the importing is not fixed. Other non ST formats may be added, and
a hook will be provided for additions.
DM print drivers are about 500 to 800 bytes
Select all objects on a page
Changing attributes for highlighted areas/ or the whole column/ or
the entire link/ or the entire document.
Snap to grid and snap to guides. Set you grid and guides.
Tabs are column oriented. Decimal, left,center right tabs. hopefully
with leaders.
Make Caps Auto justification (somewhere between char and word justify)
Paragraph formating (indent/outdent)
Lock objects down.
open ended polygons/ arcs/ elliptical arcs
reshape arcs/ polygons/ pictures
save defaults seperatly. Specify paths in a dialog box. set marcros
the old way or in a dialog box.
Any time a measurement is called for, (text size, grid xy, left/right
margins, etc) you can enter it as inches/cm/mm/picas/points/absolute
(1/3600inch)/ciceros/didot pts.
edit/add/delete words in hyphenation exception dict and spelling dict
configure for various hyphenation routines
edit/add/delete kerning pairs
Set maximum hyphens in a row/ min char before/after hyphen
move by word left/right, delete word left/right Well, I'm sure there is
more, if you don't see something, leave me a note or maybe Jack. By the way,
Jack is just a good friend of mine who calles me at odd times at night, and is
not responsible for my mistakes, etc.. He just likes to help. So be nice to
him.

Back to the pit
Deron Kazmaier (and I thought programing was difficult)

Sounds great !!

Martin Wiedmeyer writes:
>
>This is the first I've heard of the Craft development package and STedi. If
>it's faster than Tempus, I'm really interested. Where can it be purchased?
>

I am surprised that knowledge of the Craft development package has not yet made it out to usenet. While I was living in Holland I had the privilege of being one of the beta testers of this package, and since then I have come to depend on it. Since I like it so much, I will be glad to answer.

STedi is a very fast editor that was written specially for the ST. To say that it is faster than Tempus is perhaps missing the point. It is indeed faster than Tempus in many respects (for example the search/replace routine is a little faster but this can only really be seen on a file > 200K) and in a few aspects it is perhaps slower, although I am not sure. Both are so fast that the speed of the editor is no longer a factor. The important fact is that STedi is much much more powerful as an editor. Aside from all the regular features - search/replace, cut/paste, undo, etc. there are many non-standard features such as:

- 8 text buffers: switch between them at the stroke of one key.
- 10 learn buffers: record up to 100 keystrokes for replay
- complete key redefinitons: one key can be redefined to perform the action of one or more keystrokes, or even multiple keystrokes can be defined to perform the action of only one. This can be used to emulate another editor. I have seen an almost complete emulation of the Vax edt editor running.
- insertion of non-standard ASCII characters is easily done, via hex code. (combine this with key redefinitons ... - one beta tester configured STedi to type in Hebrew - complete with charcaters appearing in reverse order)
- "folds": you add a couple of lines in the program that are comments to the compiler but allow the editor to suppress all text between them at the stroke of a key, or a click of the mouse. This allows organization of the program in logical units which can be 'opened' and 'closed', sort of like an outlining feature in a word processor, but is done all in ASCII.
- cut/paste can be used only in a certain range, or just in specific columns, as well as can search and replace.
- automatic wordwrap and auto-indentation features
- edit hex code directly and write it back out to disk
- execute external programs (compile etc.) from within the editor.
- alternate fonts (fixed width only)
- save configuration (key redefinitions, fonts, numerous settings I haven't mentioned) to a file to be read at startup.
- find matching parenthesis command
- find next occurrence of present 'word'

- etc.

This is only the beginning. So you see STedi is not really even in the same class as Tempus. I should add that STedi does not use the GEM windows/menus interface although this is actually an advantage in my opinion, the way the program is written. This allows full 80 column (in fact a line can have up to 255 characters with horizontal scrolling) by 24 line editing and more if a smaller font is used, and no compromise is made with ease of use. The mouse can be used for moving the cursor, scrolling, opening and closing folds, etc. as well as for reading and writing through the file selector, cutting and pasting etc. A menu bar appears at the bottom of the screen in contrasting color (much in appearance as Uniterm), which is also used for commands. <Esc> brings the cursor there to enter commands. The status of certain modes (insert/overwrite mode, and the like) the name of the file being edited, and the current line number are printed there. Also messages appear there depending on the circumstances. This is all sort of like EVE on the Vax.

Perhaps the most outstanding thing about the editor is the paying attention to detail. For example, if you exit (one keystroke for save current buffer and exit, another for just exit) only if something is unsaved are you queried. No clicking away of unnecessary dialogue boxes, etc. (as with many of our unfavorite editors and word processors) Or when you paste something in, and realize you don't want it there, the editor is already configured to recut it out. Such time saving features can be invaluable to the programmer. All in all, aside from perhaps the LSE editor on the Vax along with some personal touches (compiled TPU additions), I have never seen such a powerful and at the same time user friendly editor as STedi, on a main frame or a micro.

STedi is being marketed as part of the Craft development package by Commedia in Amsterdam:

COMMEDIA
P.O. Box 6409
1005 EK Amsterdam, The Netherlands

The other side of the package is a Unix-like shell called the GPshell, which is also an extemely nice piece of software. Besides providing Unix replacements for all GEMDOS functions, and with standar unix features such as aliasing, history, wildcarding, redirection, pipes, etc. there are a number of non-standard features also such as the possibility to edit previous commands (more like VMS), if you start typing a file name and then press <Esc> the filename is completed for you insofar as it is unique, and a ramdisk and print spooler are included that can be created or destroyed at will from the shell. As the original question was about STedi I won't go on about the shell except to say that the two work very well together. If the shell is present, STedi can execute any shell commands besides external programs. We bought our copies of Craft (at FSU) for around $200 U.S. although the price might have gone up due to the exchange rate.

If this sounds like an advertisement, it should, because I am one satisfied user. I would like to see such an excellent product succeed. (Disclaimer:) However, I have no relation to Commedia whatsoever.

Common misconception. Compu$erve holds an ``anthology copyright'' on
their databases. This is intended to prevent other information services
from downloading and reselling the databases in their entirety.

Anthology copyright is common in the publishing industry. In no way
does it restrict the author's rights to the original material.

I am not saying have every event cause a mediach() nor do I advocate
an at random() times cause a mediach() event. Instead have the driver check
the system space available and when it gets low cause a mediach(). This
should then be an infrequent event and will in fact only occur when their
has been progression through the disk. This type of situation would be
defeating your caches anyway.

> 1) Does it speed up reading solely (i.e. is it a 'write through' cache) ?

It's write through. Writing _might_ be a shade faster (see following).

> 2) Does it solve the TEDIOUSLY SLOW writing problem on not too empty
> partitions ?

Nope. It might help a little due to the FAT and directory tending to
be cached, but the bulk of the slowness is in GEMDOS's FAT searching
routine.

> 3) Does it solve the 40 folder bug ? AND/OR

Nope.

> 4) Does it work correctly with FOLDRxxx.PRG ?

Can't imagine why it wouldn't. I use GEMBOOT, which is similar to FOLDRxxx.

What would really be nice is if everyone could access all the servers. Some
of us, me for instance, can't get to Houston at all. In the interest of
bringing about the widest possible distribution of information and programs,
I would like to suggest that the people who run the servers at Canada and
Houston (and elsewhere including a new server in England I just read about)
get together and try to maintain a common set of files. I appreciate the
effort these people put forth just to make life easier for the rest of us.
If everyone could access all the files planted on servers, then even more
could we appreciate and applaude their efforts.

I am also a BSD 4.3 user at work, and use Gulam at home on the ST and love it.

Just now, on the ST, I typed the two commands:

```
help > tt
sx tt # to upload to the unix system (built in x-modem
```

Not everything behaves exactly the same on Gulam. Prof. Mateti, the
author, has some ideas about consistency of syntax. For example,

In 4.3BSD csh In Gulam

```
setenv aaa "hi there" setenv aaa "hi there"
set bbb = "hi there" set bbb "hi there"
echo $aaa $bbb echo $aaa $bbb
```

It also has something called "ue" which is some flavor of micro-emacs.
It is NOT un*x, but it is a simple, expanding shell done in that spirit.
The electronic address for P.Mateti shows below, but the shell is
available from a number of bulletin boards, and from
LISTSERV@CANADA01.bitnet.

Here is the file "tt".

```
------------------------------------------------------------------------
beta-test version 1.00.00.00 101887 of
yet another shell for atariST

(non-profit redistribution is permitted)

/gulam. Copyright = 1987 pm@cwru.edu

62 built-in commands:
alias dm endwhile help more printenv set ue
cat dirc exit history mson pushd setenv unalias

There are two issues.

My original posting was a suggestion as to why there is a shortage of
real software for the ST. I do not consider FoReM in that category.
Its something I do in my spare time. Atari cannot attract "real"
software companies to support the ST when in 3 years they have not
addressed the easy or the most obnoxious bug in Gemdos.

That was what I was aiming at. The issue of continuing support for my ST software has nothing to do with this. Or almost anyway... The smaller the market, the more of a problem piracy is. And the ST market will remain small as long as the base of "real" software is limited. And this base will remain small until such time as Atari deceides it is in its own best interest to support the ST like a "real" computer vendor.

Another amusing issue:

I find it truely fascinating all this discussion about David Beckmeyer releasing RTX into the public domain. I can't believe how few people even knew it existed. They want it free, but are willing to pay a small amount for the docs. Well I have news for you all, its never NEVER been that cost prohibitive. All of 69.95 list and its been around for about 2 years... How can you expect him to support it for less?

You mean like one of the GIMIX 6809-based SS-50C bus computers? The price may be a bit steep for "home" micros, but they've been around for years, and the memory management does have teeth in it. OS-9/6809 Level Two runs quite nicely on them.

I don't know enough about the GIME chip in the CoCo 3 to be able to say how protected processes are from one another--they *do* have separate address spaces, though, and the price is certainly in the "home" computer range. You might want to pay a visit to someone who owns one and runs OS-9 on it.

1904. Wanted: dvist

Newsgroup: comp.sys.atari.st
Date: 1988-02-20 17:42:21 UTC
From: leo@sunybcs
Message-ID: <8698@sunybcs.UUCP>
Source record: 254405

Can anyone point me to an ftp address for dvist, the DVI file previewer for the ST? I have tried radc-softvax and score.stanford.edu w/out success. Score has a file called dvist.ntxt.1, but when I transferred it I found myself with something that was unusable. At least, I couldn't figure it out. Any help would be appreciated. If noone knows where to get it via anonymous ftp, is it possible that someone who does have it can mail me a message to that effect, so that if I can't find a way to get it myself I might grovel for it from you in a week or so? Thanks, -Leo
P.S. As long as I'm at it, does anyone have sources for the newest Dmas uucoding package? Sure would be nice to have it on this host as well as at home... Obviously MUCH better than standard UNIX uucode.

No doubt CompuServe could claim that uploading software to its machine
(or allowing others to do so) constitutes permission to include that
software in its "compilation".

Don't bet on it...as I recall from the booklet on corporate security
they gave me when I first went to work, the only ABSOLUTE way to
secure the copyright on the document is with the symbol-which-is-
usually-approximated-by-(c). You know, the small letter c with the
circle around it. The c with parentheses doesn't cut it, neither
does "Copyright (c) 1988 by Nick Thompson. All Rights Reserved."
Of course it doesn't hurt to put that in, and it will certainly
give you some protection, but apparently the letter of the law says
that you need the little symbol that isn't in the ASCII character
set. So how do you protect your source code? Well, all the stuff
mentioned above counts for something, I hope...

If you want, I'll look this up and quote later.

hello there .....

I am looking for a copy of the mx2 operating system. In a recent posting
someone stated that it was available on the gateway bbs. I have tried
to cal the bbs, but have failed in all atempts. Could some kind soul out
there either send me a copy of mx2 or tell me what the protocol is for
the gateway bbs?

I tried several times to call gateway, but I think I am using the
wrong protocol. This is despite the fact that I tried every possible
combination of bits and parity etc.. that I know of. I did get a hold of the c
omputer though when I called. What is the protocol used?

Thanks in advance for any replies.

From: Gribnif@umass
Message-ID: <8802210020416D5.BLBS@Mars.UCC.UMass.EDU>
Source record: 254416

Greetings!

Is there some way to actually "tell" desk accessories that are currectly opened within an application to close? I am writing a program that uses Pexec() to call other programs, but the problem I am running into is that any DA's that occupy windows and are left open when my program executes another do not receive the AC_CLOSE message and so do not know they should be closed. Of course, I cannot simply close their windows for them; that only messes them up. Pterm() somehow does this for itself since it automagically sends the correct message when the application terminates. shel_write() also seems to suffer from this same problem. Is there any good solution, short of hacking-into the OS?

1916. Pexec Cookbook

Newsgroup: comp.sys.atari.st
Date: 1988-02-21 07:32:17 UTC
From: uace0@uhnix2.UUCP
Message-ID: <498@uhnix2.UUCP>
Source record: 254417

Here is the Pexec cookbook, plus some information posted by Alan Pratt some time ago.

================ like cut here like ==========================

This is in response to a request from Christian Kaernbach which I got from BITNET: I can't reply directly to BITNET, but I'm sure other people will find this interesting, too: it's a preliminary version of the long-awaited Pexec cookbook!

In broad terms, the things you have to know about Pexec are that it starts up a process, lets it execute, then returns to the caller when that process terminates. The "caller" -- the process which used Pexec in the first place -- has some responsibilities: it has to make memory available to the OS for allocation to the child, and it has to build up the argument string for the child.

All GEMDOS programs are started with the largest block of OS memory allocated to them. Except in very rare circumstances, this block is the one stretching from the end of the accessories and resident utilities to the beginning of screen memory. The point is that your program has probably been allocated ALL of free memory. In order to make memory available for a child process, you have to SHRINK the block you own, returning the top part of it to GEMDOS. The time to do this is when you start up.

If you use Alcyon C (from the developer's kit), you know that you always link with a file called GEMSTART. If you've been paying attention, you should have gotten the *new* GEMSTART from Compuserve (or from somebody else who got it): I wrote that GEMSTART. In GEMSTART.S, there is a lot of discussion about memory models, and then a variable you set telling how much memory you want to keep or give back to the OS. Make your choice (when in doubt, use STACK=1), assemble GEMSTART.S, call the result GEMSEXEC.O (or something), and link the programs which Pexec with that file rather than the normal GEMSTART.

Now here's a discussion of what GEMSTART has to do with respect to keeping or returning memory:

Your program is invoked with the address of its own basepage as the argument to a function (that is, at 4(sp).l). In this basepage is the structure you can find in your documentation. The interesting fields are HITPA (the address of first byte NOT in your TPA), BSSBASE (the first address of your bss) and BSSLEN (the length of your BSS).

Your stack pointer starts at HITPA-8 (because 8 is the length of the basepage argument and the dummy return PC on the stack). The space from BSSBASE+BSSLEN to your SP is the "stack+heap" space. Library malloc() calls use this space, moving a pointer called the "break" (in the variable __break, or the C variable _break if you use Alcyon C) up as it uses memory. Your stack pointer moves down from the top as it uses memory, and if the sp and _break ever meet, you're out of memory. In fact, if they ever come close (within a "chicken factor" of about 512 bytes or 1K), malloc() will fail because it doesn't want your stack to overwrite good data.

When a process starts, it gets *all* of memory allocated to it: from the end of any accessories or resident utilities up to the default screen memory. If you want to use Pexec, you have to give some memory back to the OS. You do this with the Mshrink call. Its arguments are the address of the memory block to shrink (your basepage address) and the new size to shrink it to. You should be sure to leave enough room above your BSS for a reasonable stack (at least 2K) plus any malloc() calls you expect to make. Let's say you're writing "make" and you want to leave about 32K for malloc() (for your dependency structures). Also, since make is recursive, you should leave lots of space for the stack - maybe another 16K. The new top of memory that your program needs is:

newtop = your bss base address + your bss size + 16K stack + 32K heap

Since your stack pointer is at the top of your CURRENT TPA, and you're about to shrink that, you'd better move your stack:

```
move.l newtop,sp
```

Now you want to compute your new TPA size and call Mshrink:

```
move.l newtop,d0
sub.l basepage,d0 ; newtop-basepage is desired TPA size
move.l d0,-(sp) ; set up Mshrink(basepage,d0)
move.l basepage,-(sp)
move.w #$4a ; fn code for Mshrink
trap #1
add.l #10,sp ; clean up args
```

Now that you've shrunk your TPA, the OS can allocate this new memory to your child. It can also use this memory for Malloc(), which is used occasionally by GEM VDI for blt buffers, etc. Note that you only have to do this once, when you start up: after that, you can do as much Pexec'ing as you want.

When you want to exec a child, you build its complete filespec into one string, and its arguments into another. The argument string is a little strange: the first character of the argument string is the length of the rest of the string!

Here is a simple system call: pass it the name of the file to execute and the argument string to use.

```
long system(cmd,args)
char *cmd, *args;
{
char buf[128];

if (strlen(args) > 126) {
printf("argument string too long\n");
return -1;
}
strcpy(buf+1,args); /* copy args to buffer+1 */
buf[0] = strlen(args); /* set buffer[0] to len */
return Pexec(0,cmd,buf,0L);
}
```

The first zero in the Pexec call is the Pexec function code: load and go. The cmd argument is the full filespec, with the path, file name, and file type. The third argument is the command-line argument string, and the fourth argument is the environment pointer. A null environment pointer means "let the child inherit A COPY OF my environment."

This call will load the program, pass the arguments and environment to it, and execute it. When the program terminates, the call returns the exit code from the program. If the Pexec fails (not enough memory, file not found, etc.) a negative code is returned, and you should deal with it accordingly. Note that error returns from Pexec are always negative LONGS, while return codes from the child will have zeros in the upper 16 bits.

EXIT CODES:

GEMDOS, like MS-DOS before it, allows programs to return a 16-bit exit code to their parents when they terminate. This is done with the Pterm(errcode) call. The value in errcode is passed to the parent as the return value of the Pexec system call. The C library function exit(errcode) usually uses this call.

Unfortunately, the people who wrote the startup file for the Alcyon C compiler didn't use this. The compiler calls exit() with an error code, and exit() calls _exit(), but _exit always uses Pterm0(), which returns zero as the exit code. I fixed this by rewriting GEMSTART.S, the file you link with first when using Alcyon.

Even though new programs return the right exit code, the compiler itself still doesn't. Well, I have patched the binaries of all the passes of the compiler so they DO. It isn't hard, and I will post instructions at a later date for doing it. IF YOU DO THIS, PLEASE DON'T BOTHER OUR CUSTOMER SUPPORT PEOPLE IF IT DOESN'T WORK. THEY DON'T KNOW ANYTHING ABOUT IT.

I hope that this little cookbook makes Pexec less mysterious. I haven't covered such topics as the critical-error and terminate vectors, even though they are intimately connected with the idea of exec'ing children. A more complete cookbook should be forthcoming.

If there are any errors or gross omissions in the above text, please
let me know BY MAIL so I can correct them coherently. Landon isn't
here to check my semantics, so I may have missed something. [Landon
is on vacation in France until early September.]

****

C. Kaernbach's question was why his accessory, which basically did
a Pexec from a file selector, didn't always work. The answer is that
it works when used within a program which has returned enough memory to
the OS for the child. Why might it bomb? Because if a program has
returned a *little* memory to the OS (only about 2K), a bug in Pexec
shows up that breaks the memory manager. Accessories are strange beasts
anyway, so for the most part combining two strange beasts (Accessories
and Pexec) is bad news.

here is additional info

================== like cut here again like ======================

Attention Mark Williams, Beckmeyer, and Gert Poltiek, and anybody
else interested:

There is a trick that some shells and compiler libraries use that lets
you pass argument strings to programs which are longer than the 127
bytes which fit in the command line area of the basepage. Their trick
is to put the word ARGV= in the environment, and follow it with a
null-separated list of argument strings. The list is terminated with
another null.

This scheme works pretty well, but has two drawbacks, one major and one
minor.

The minor drawback is that it defies the definition of what is in the
environment: the environment should consist of strings of the form
NAME=value<NUL> terminated by a final <NUL>. This is minor because
shells using this convention usually put the ARGV information at the end
of the environment anyway.

The major drawback is that you can't tell if the ARGV string in your
environment is really meant for you. Imagine you have the Mark Williams
shell (msh), an editor compiled with Alcyon, and another utility like
"echo" compiled with MWC. Imagine further that the editor has a
"shell-escape" command that lets you execute another program from within
the editor.

Do this:

From msh (the MWC shell): start up the editor with the
command line arguments "this is a test."

Tell the editor to execute the command "echo hello world."

The "echo" command will echo "this is a test," not
"hello world."

What happened is that msh put "this is a test" in the environment for the editor (as well as in the command tail in the basepage). The editor, not knowing any better, didn't put "hello world" in the environment before executing "echo." When "echo" started, it found "ARGV=this is a test" in its environment and echoed that.

What is needed is a way for a program to tell if the "ARGV=" string in its environment is really intended for it, or is just left over from an earlier program. There is a way to do this that doesn't affect old programs compiled without this fix.

The new convention could be to place another string in the environment with your own basepage address, before Pexec'ing your child. The child could start up, and check to see if its parent's basepage address (in its basepage) matches the address in the environment. If it does match, the child will know that the ARGV= string is for it. If it doesn't match, the child will know it was started from a non-MWC program like the editor above, and will look in its basepage for the command line.

Note that if the parent's basepage isn't in the environment at all, but the ARGV= string is, the child must assume that the ARGV string is intended for it, just as it does now. Therefore, old-style programs could still Pexec new-style children, and vice-versa.

This would all require a change in the startup code that calls main(), and the exec() code which Pexec's the child.

How about it, guys? If we could all agree on the name and format of this new environment variable, we could get rid of a serious flaw in Mark Williams' otherwise clever scheme. Other shells could adopt this, too, and ultimately everybody would be able to kiss the 127-character command-line limit goodbye.

For now, I propose that the environment variable in question be called PBP, and that its value be the decimal string of digits making up the parent's basepage. The reason for this is that almost all libraries have an atol() function, where not all have an atolx() function.

A shell using this trick, with a basepage at 366494 (decimal), could Pexec a child called "test.prg" with these strings in the environment:

```
...
PBP=366494<NUL>
ARGV=test.prg<NUL>first<NUL>second<NUL>third<NUL><NUL>
```

In the startup code of the child, you would do something like this:

```
If there's a PBP= in the environment
If atol(PBP) == my parent's basepage
get args from environment
```

```
else
get args from command line
endif
else
if there's an ARGV= in the environment
get args from environment
else
get args from command line
endif
endif
```

Does this sound reasonable? I would like to see this kind of thing become a standard, but until a safeguard like this is in place, I can't condone using ARGV= in the environment for finding your arguments. It's too chancy just to assume that you were started by a program savvy to this scheme.

1917. Re: RAM disks

Newsgroup: comp.sys.atari.st
Date: 1988-02-21 14:52:42 UTC
From: achowe@trillium.waterloo.edu
Message-ID: <5269@watdragon.waterloo.edu>
Source record: 254418

The good news...

I don't know if this will help, but "Compute!'s Atari ST" magazine
Issue 5, Vol 2, No.3 provided a recoverable RAM disk which recovered
from system crashes 90% of the time. Mag/disk provided both .TOS and
.S files. It was totally configurable for size, drive name, and files
to copy to the RAM disk. I used it from the time it came out on my
1040 ST till I switched to a Mega ST2...

...the bad news...

Except this gem of a program which was to be the corner stone of my
development environment (1M recoverable RAM disk, wow!) does NOT
work on the MEGA ST2 (gasp!!). What seems to happen is this, the disk
sets up just fine from cold boot, but when you attempt to reset the
system after a crash, the RAM disk program says it recovered
(which I have determined to be true because a tool I have says the
system is short 1M of memory after the reset) BUT fails to connect
the RAM disk with the GEM icon for that disk. As to whether or not the
RAM disk's data is intact, I have not been able to verify since I
can't access it.

I've been meaning to write the magazine and tell them to notify the
author and/or have a look at the code myself but haven't as yet had
time to play with it.

Maybe *hint, nudge, poke, beat with large stick* if someone else
could take a look at this fine program that doesn't seem to work
to specs on MEGAs (grrrr) it might be possible to fix a bug or
create a MEGA version. The magazine copyright does not allow me to
pass the source around :-(

I think this is basically right. The trick is the word _absolute_.
*In*the*United*States*, the word "Copyright" (or the abbreviation "Copr")
is fully adequate. But _internationally_ things are slipperier. This
from "Words Into Type":
Universal international copyright protection does not exist. However,
works of Unisted States citizens may be protected in foreign countries uner
various treaties and conventions. Copyright protection is available in
countries currently parties to the \fIUniversal Copyright Convention\fP,
provided that all the published copies of the work bear the notice
precscribed by the \fIConvention\fP, that is, the symbol \(co, the name of
the copyright owner, and the year of first publication. ...

Due to the increasing infringment of my job on my free time (how dare they (;-)
I find that I do not have the time to maintain comp.binaries and comp.sources
the way they should be. Therefore I am withdrawing as moderator of these
groups, if some brave person would like to pick them up, please send me email
and I will send you the archives, programs etc.

Actually I am telling a half truth, it is also Atari's approach to the software
side of the business that has disheartened me somewhat, they seem to feel that
software is of secondary (if that high) importance and the malaise is infect-
ious. I have not stated this as well as I wanted to, but....

>

I sent for copyright info booklets from the government 1 or maybe 2 years ago.
It said thus:
Copyright 1988 Joe Hitchens All Rights Reserved (is correct)
Copr. 1988 Joe Hitchens All Rights Reserved (is correct)
(c) 1988 Joe Hitchens All Rights Reserved
(where the "(c)" is actually a small c in a circle is correct)
(c) 1988 Joe Hitchens All Rights Reserved
(where the "(c)" is a c in 2 parenthesis is NOT correct)

In my case, I have always gone with the:
Copyright 1988 Joe Hitchens All Rights Reserved
It seems the most official looking.

NOTE: Despite all the visible copyright messages in this text,
I would like to make it clear that this text is actually NOT
copyrighted but, but rather just a discussion of copyrighting
practices. (In case anyone has a weak heart.) :-)
It is actually in the Public Domain.

>hard disk's file structure to it.")

Thats awfully true. I just recovered my harddisk from the backup...

I found out what this book is, and what it cannot give you: it is not
the compileble source of gemdos/bios/xbios.

It just gives you a closeup to the system. It gives a lot of hints to
beware sections and lists a couple of serious bugs.

I just hope there ist somebody with a C-Compiler *and* the complete
source (no ampersands missing...) who will recompile it and give us an
update.

1922. 6850 handler woes

Newsgroup: comp.sys.atari.st
Date: 1988-02-21 23:51:25 UTC
From: mjs@ernie.Berkeley.EDU
Message-ID: <23078@ucbvax.BERKELEY.EDU>
Source record: 254422

Several weeks ago we started porting an application written in Forth (with a good deal of assembly thrown in for good measure) from the ST to the Mega ST. Most of the problems we had were due to use of undocumented features of TOS, et al; and unfortunately those of us doing the port were not the ones who wrote the bulk of the suspect code, so we don't even know how we found out about these undocumented goodies.

There are two vectors - one at 114 and one at 118 - that are used by the program (and changed). Although the Abacus book doesn't know about these, it seems to be common knowledge (?) that these are the timer interrupt and the 6850 handler respectively [perhaps this information is in the Developer's Kit, which is on order]. These vectors seem intact on the Mega, but the 6850 handler calls the keyboard handler and the MIDI handler explicitly, and those addresses, which are hardcoded into the handler, have changed. Our desire is to intercept only MIDI interrupts; we do this by intercepting 118, checking to see if the MIDI 6850 requested the interrupt, and passing control to the keyboard handler (whose address we learned from disassembling the original 6850 handler) if not. The problem is, of course, that this address may change again, and in any event, it requires different versions of the program for each TOS version.

Is there Another Way to accomplish all this in a more portable fashion? Will the Developer's Kit answer these questions (and more)?

Waitaminute! What if you don't *have* an atari dot-matrix printer? In my case, for example, I've got a Panasonic KX-P1091 (Epson FX compatable [I think, somebody lemme know if I'm wrong])...Does this mean that if I get Microsoft Word for the ST, I *CAN'T* use the graphics printing/custom fonts on my setup?

Maybe I'm stupid, but why doesn't Atari include GDOS drivers for other printers in the package, then? On the other foot, if I've read the above quote wrong, will somebody correct me?

Thanks a bunch,

--R.J.
B-)

P.S. 1st Word is great, but if I can get MW to work (and get all them nifty fonts and tricks, too), then I'll buy it...

WRONG: Copyright or Copr. instead of the "c in a circle" is perfectly OK.

If you don't know what you are talking about, why don't you shut up.

>I asked this question before, back in October '87. Mike Fischer

I asked the same question a year ago when I was writing HDSCAN. Had the same problem, but since HDSCAN wasn't really intended to do much heavy work FROM the floppy, I decided to hold of on the workarounds. I tried LOTS of permutations with doing FSFIRST, etc. It would work sometimes, but not reliably. I just got through writing a new program that has to read the floppy subdirectories, but now I can't get the problem to pop up at all. I am using MWC 2.xx (I originally had the problem on MWC 1.x and OSS Pascal 1.xx both of which are dust now). The file open calls I am currently using to open the files for access are Fopen and fopen (don't ask...) and I do try to open a file at the root level (either a direct file or the volume name...doesn't matter) before any access to the sub-directories on the disk.

This is one of those problems that makes it so fun when I port my code back and forth between the ST and Unix...

-Todd Burkey

(Yes, Jim S...DISKSCAN is now done and you really will get the first copy! And the TOOL-WARE version will be in the Snail Mail to those of you patient people who liked DISKTOP enough to send in $$. Note that I am hesitant to use the 'S' ware word on the net after all the strange arguments that pop up when people see it :-). Oh, BTW, DISKTOP is shelved until OSS Pascal 3.00, or whatever version, fixes the flakiness in 2.xx. I don't expect any future for DISKTOP with DISKSCAN available, anyway...)

From article <346@coma.UUCP>, by axel@coma.UUCP (Axel Mahler):

> No benefits ?! It's a major nuisance to always think of moving those
> f&*%ing resource-files around together with the programs. Separate
> resource files are also a violation of GEM's idea of (well, kind of)
> 'object oriented-ness'. It's, for instance, not possible to open files
> of a given type with some (application-) program if the resource file
> for that program happens to reside in any other but the current
> directory.

That's not entirely true. Your .RSC files don't _have_ to be in the
current directory. If you set your PATH environment variable to:

PATH=c:\bin

GEM will look in c:\bin for the application and any .RSC files.

The problems are:

1. GEM doesn't provide any way of setting the environment variables.

I use GEMBOOT, which provides a means of setting the environment
variables _before_ the desktop comes up.

2. The application may look for other required data files in the
current directory.

I consider this bad design on the part of the application. Does
anyone out there have a work around (not including copying the
application's data files into all directories :-) ?

3. The path seperator character expected by GEM is ';' (semi-colon).

I use MWC's msh, Beckmeyer's Micro C-shell, and Gulam. They all
use ',' (comma) as a seperator. This caused two problems that
confused me for quite a while:

1) GEM applications invoked from a shell didn't always work.

The problem was that GEM didn't grok the PATH set up by the shell,
and the application couldn't find it's .RSC and other files.

2) The shells couldn't handle the PATH set up for GEM.

I used to set up PATH as:

PATH=C:\APP;C:\BIN;C:\ETC;C:\

which worked fine from the desktop, and GEM could find
application's and their .RSC files in any of the listed
directories.

The problem was that seemed to confuse MWC's msh. It couldn't
seem to find it's startup file "profile" no matter _where_ I put
it. The symptom was some obscure message (like "End of file in '"),
which didn't help in finding the problem.

There is an AES function: shel_find() that will search through the
directories listed in PATH for the given file name, and returns the
full path for the file if found.

Now, if shel_find() recognized ',' as a delimiter, or if all the
shells used ';', all this would work together rather nicely...

(BTW, if I got any of the above wrong, I'd love to be corrected :-)

In article <909@xn.LL.MIT.EDU> singer@XN.LL.MIT.EDU (Matthew R. Singer) writes:
>Why does tos sometimes say a file is not there when it is, if the
> file has been added to a disk after some subdirectories have been
> added?

Don't know about most of the things Matthew is on about -- though I would agree that Atari do appear not to be the speediest folk in the world; and that they need to improve both 'fix output' and 'documentation' if they want to be taken seriously as professional machines. However...

Apropos of the particular question quoted (and the converse, why does TOS sometimes say a file is there when it isn't), a warning... (I'm not saying it can't happen at other times, but) the only time I've seen either of these effects, it's because the system has been fed 2 disks back-to-back which have the same 'unique serial number' in the header block. This is a 24-bit number generated randomly by the standard disk format routine, so the odds are very much against your ending up with a matched pair if you use the standard desktop formatter.

HOWEVER, some of the PD formatters (only the first version of TWISTER, to my knowledge, but might be others) had a bug which meant that they would format all your disks with the same number.

OR, if you use a 'bit-copier' ('backup-utility', 'protected disk copier', ... ProCopy which i use comes to mind) then, BY DEFINITION, the copy of a disk which it makes you will have the same unique serial number as the original. If you then actively use both disks you'll have this problem. (At one point, the ProCopy folks decided to make 'twisted' format generally available, by distributing ProCopy on a 'twisted' disk, and telling you you could get other 'twisted' disks by bit=copying their disk and deleting all the files. They very rapidly backed off from this. The problem is obvious.)

OR, I would also bet that if you have multiple ORIGINAL copies of the same commercial product, the disks will be IDENTICAL including the unique serial number -- whether for protection, or for ease of production, doesn't matter.

I trawled through my disks the other day and found 3 disks with identical serials (all began as bit-copies of a single disk). Re-arranging to fix that has eliminated some annoying little glitches. (I'm fortunate in that all 3 were disks I use write-protected, so I didn't actually manage to garbage any of them.)

If you are experiencing this sort of problem, THINK about whether any of the above cases might hold. (If you've got a disk doctor, look at the 24-bit number at offset 8 from the beginning of the boot block (sector 0) on the

disks -- the disk showing the problem, and the disk you had in that drive immediately previous.) If you do have pairs or sets with matched unique IDs, you will eventually regret it.

i determined this by find the same problem with the mouse (the pointer didn't
always move where you wanted it to... sometimes, it would just hole itself
up in a corner of the screen and stay there) when i tried it on another
machine.
<
I had my 520STFM for about a month when this happened, despite buying the mouse a mousemat to run on. I know what caused it. It was all those people coming to my place, commandeering the machine, and playing Star Wars on it.

Anyway, being hardware-orientated, I couldn't face sending the mouse in for replacement unquestioned so I disembowelled the little so-and-so.

There is a big ball in it which drives two dual rotary optical switches by means of little drive wheels. There is also a spring-loaded idler which keeps the big ball in place. Both of the drive wheels and the idler were encrusted kind of goo. This was made up apparently of carpet fluff, cat hair, and other less mentionable organic debris, I guess.

So I took a toothpick and spent half an hour scraping off the goo - the carpet fluff etc. came out with a pair of surgical tweezers. I polished up all the little wheels with isopropanol and a Q-tip, amid hoots and jeers of derision from the frustrated Star Wars players, who were getting restless.

On reassembly the mouse worked as new, and they took my computer away again and played the damn game until 0330.

This was the standard Atari mouse. Compared to a Xerox optical mouse it is not very good, so I'm still working on improvements.

Suggestion: if you try this for Pete's sake keep your Q-tip away from the optical gear since the cotton will get wound around the shutter shafts and in amongst the IR optoswitches. Don't use anything metallic on the wheels; toothpick (wood or plastic) is OK. Clean the big ball as per Atari instructions.

I'll try to get one of the other sort of mice and disembowel that, too. I was thinking maybe one could build or modify mice; they're not apparently all that complicated. Anybody tried it?

Regards,

Chaz

Axel, sorry but that's not true (I've mentioned this before...),
rsrc_load uses the GEMDOS search path to find .rsc files. So I've
got gemboot to set the path to something like:
PATH=;C:\;D:\;E:\;D:\UTILITIE.S\;
if I'm currently in C:\ASSEMBL.ER and double click a .s file, I can
have a application start up which is anywhere in the search path and
it WILL find it's .rsc file.
Another advantage of .rsc files, is that they can (in theory) be translated
to another language, without recompiling the program.

> Does someone know the format of the *.bin object files and the format of the
> *.bin libraries supplied with the compiler? Perhaps it would be possible to
> write my own librarian.

The GST Linker used by Lattice C does not have a "library" format.
The library files are just concatenations of object files. If you
have a shell of any sort, you can add a file to a library as follows:

```
mv library.bin temp.bin
cat temp.bin newfile.bin > library.bin
rm temp.bin
```

Extracting a file out, or removing a file, would be trickier: you
would have to read the header information for the first object, skip
over it, read the header info for the second object, and so on until
you came to the file you want.

>a lack of postings...

I've been waiting some time for this matter to come up.
Richard, comp.{sources,binaries}.atari.st used to be moderated
newsgroups, meaning that not just EVERYbody is allowed to post his
junk there. However, moderated newsgroups completely rely on a
MODERATOR doing his job REGULARLY. Unfortunately, in this particular
case, the moderator has obviously disappeared from the net without
notice.

> Does this mean I have to sift through comp.sys.atari.st to find the
>programs I want ?
>
I'm afraid this DOES mean you (and I, and many others) have to
sift through this noisegroup. I see three possible solutions to the
current dilemma:

1. Find someone reliable with enough time and suitable resources,
and make that person the new moderator of comp.{src,bin}.st.
2. Make both newsgroups unmoderated or,
3. rm-group both groups and return to the way programs have been
distributed before - through comp.sys.atari.st.

Currently breaking its way is 'solution' no. 3. I hate the idea.
I'd be very much in favor of no. 1, but - in case nobody volunteers -
would prefer no. 2 over what's going on now.

I'd like to hear about other ideas, or how you folks out there feel
about the current situation, and my suggestions.

cheers, Axel.

1935. DBs for ST

Newsgroup: comp.sys.atari.st
Date: 1988-02-22 16:13:51 UTC
From: wsl@erc3bc.UUCP
Message-ID: <16@erc3bc.UUCP>
Source record: 254435

A while ago I posted a request for some information on Database programs available for the ST. I have yet to see or receive any responses so I'll just have to try again.

Just some short answers to few questions:

(1) What is considered the best relational Database product available?

(2) Is there now (or will be in the near future) a SQL based database available for the ST?

(3) Is pc-ditto a worthwhile product?

(4) Would it be practical to run an MS-DOS DB package on the ST using pc-ditto?

I hope someone will post a response. Any and all are much appreciated. (I also want to make sure my postings are getting out to the net).

Thanks in advance,

Warren S. Lobel

>Matt Singer
>Commnet Systems

From many people I've talked to, Matt echoes the feelings of a large
number of ST developers. I think it's a darned shame, and really
says something about Atari and the future of the ST. For all of us
that have dumped $$$ into this, we're the ones that really suffer.

As Atari loses developers and product support, those of us with STs
are getting stung; and Atari still has big $$$ in the bank that they
don't want to spend to improve things. I just can't figure it.

The ST can't attract big companies and Atari won't help the smaller
companies that took a big risk developing for the ST. And in the
end, it's the ST owner that gets screwed, as companies are forced to
drop their support for Atari, and many end up going out of business.

But then next year Atari announces a new product and sells a bundle
to the next generation of suckers (those that haven't been burned yet).
A new pile of hopefull software developers work their b*tts off to get
some new nifty software developed (with little or no help from Atari)
and Atari makes a ton of $$$ off the deal, at everybody elses expense!

I wish Matt all the best!

> will not work !!
> /leonard

Oh, come on now. I've done quite a few upgrades with Samsung and OKI chips. I should add, the only one that ever went bad had Samsung chips. For that reason, I stay away from them. But they certainly will work. One should also be using 120ns chips, as a precaution. The newer STs have been outfitted with these (for a reason, I would imagine, if not only because Atari could get a better price on them than 150ns).

>> ... but Beckemeyers hard disk accelerator seems to do a good job too ...
>
>Can anybody that uses the hard disk accelerator (or the author) give us some
>more information on what it does, especially :
>
> 1) Does it speed up reading solely (i.e. is it a 'write through' cache) ?
Yes, it is 'write-through' cache. It doesn't always write-thru actually, but
it *never* buffers the writes for later (i.e. it always physically writes
to the disk). It attempts to make an intelligent decision about when to
write-thru the cache (which costs the extra memory move), and when to simply
dump the buffer.

HD accel. is a "priority" LRU cache. The criteria that establishes
"priority" are:
a) is it FAT info?
b) is it directory info?
c) is it "a long way from the last head pos."
Hd accel's main goal is to reduce those long seeks which are slow. Caching
data on the ST is not as important becuase in fact the DMA rate for large
data xfers is *faster* than a CPU block move. What costs is moving the
disk heads. That's why FAT and directory info has priority over data.
>
> 2) Does it solve the TEDIOUSLY SLOW writing problem on not too empty
> partitions ?
Becuase HD accel. is write-thru, one might think that it is no help to
writing files. But this is not true becuase TOS has to do a lot of reads
of FATs and dir. info to write to a file. HD accel doesn't help a lot
with the slow FAT searches, becuase this is more CPU bound with TOS, but
it does help with writing.
>
> 3) Does it solve the 40 folder bug ? AND/OR
No. It makes no attempt at this.
>
> 4) Does it work correctly with FOLDRxxx.PRG ?
As far as we know, it works fine. If there are any problems, they have not
been reported to us. There have been very few compatibility problems with
HD accel. since Fall '86. The only known problem is with the new ICD disks
(a bug in the ICD drivers).

Wrong. To get something ready for use by others involves:

1. Writing a manual.
2. Making a serious attempt to verify that everything works -- not
just what you used.

I put substantial effort into it before distributing it as shareware --
easily 20-40 hours. (Verifying all the funny combinations of Epson
control codes is not trivial).

Source record: 254441

I got a look at Microsoft word the other day. Its a really nice program -
a bit slow though. The one thing that pissed me off was that you need an
atari laser printer to print fonts. Why is this? Why not provide a set of
dot matrix fonts (as on the mac) so people with cheap printers can get good
looking output. The lack of non-laser fonts cripples this program and makes
probably the best word-processor for the ST - almost useless!
(Yes - I know there is a metafile to postscript converter but if I had a
postscript printer I wouldn't be compaining)

1942. Re: enforcement of Sharewar

Newsgroup: comp.sys.atari.st
Date: 1988-02-22 18:44:15 UTC
From: bts@sas.UUCP
Message-ID: <348@sas.UUCP>
Source record: 254442
Cross-posted to: comp.sys.amiga,comp.sys.misc,comp.sys.ibm.pc,comp.sys.mac,comp.sys.atari.st

Just last week, I sent in about $200 for various and sundry shareware programs. However, I had been using many of them for an entire *year* (since I got my Amiga) before I got around to it. This is a general problem: even the best-intentioned people don't have any motivation to pay for shareware soon. Had I stopped using my Amiga---or even some of the software---before the year was out, the authors would never have been paid for their efforts.

For example, I stopped using vdk: some time ago. I went commercial in the meantime, and John Toebes went around hitting up on everybody for $10, but had that not occured, I never would have paid for it even though I used it for six months. (vdk:, by allowing the ramdisk to survive warm boots also insures that memory fragmentation survives warm boots, in case you wanna know why I stopped using it.)

Also, I fail to distinguish between shareware and freeware. Except for one group of simple programs which specifically stated that the author wanted no money for her efforts, I sent in contributions according to how useful I found them to be regardless of the pleas that the authors made.

If people wish to be paid for their efforts, they need to do something to motivate people to pay within a reasonable period of time. For example, the program might start up with an informative HELP panel as shipped. This would serve two purposes:
1. For people who are new to the product, it tells them how to use it.
2. For people who have been using it for a long time, it gets annoying.

When the users register, they are given an incantation to get rid of the automatic HELP on startup. This has the beauty that it is actually *helpful* for people who are starting to use it, but it still motivates people to pay before it gets too old.

The other possibility is to only print the HELP if some companion file does not exist, and then create it. If you notice that the companion-file is more than, say, 45 days old, you could then start asking for people to please send in contributions. Of course this can be easily defeated, but the point is to spur honest people to getting around to it, not to keep dishonest people from taking it.

Just one thing: If it is shareware (and you are going to do any of these things) rather than freeware, you *MUST* make this clear in any summaries on BBS's, at the top of the README file, in net communication, &c. It is not fair to pull such tactics on unsuspecting users. If you do, they will rightly resent you and feel that you are not being honest, making them less likely to pay you.

If the bottleneck is in moderation, why not just make comp.binaries.atari.st unmoderated and post binaries there? I agree with Richard Lloyd that one shouldn't need to sift through comp.sys.atari.st just to find programs that one wants. Surely posting unmoderated binaries to comp.binaries.atari.st is better than posting unmoderated binaries to comp.sys.atari.st!

1945. GDOS / Fonts / EasyDraw Questions

Newsgroup: comp.sys.atari.st
Date: 1988-02-22 20:55:36 UTC
From: tim@brspyr1.BRS.Com
Message-ID: <2712@brspyr1.BRS.Com>
Source record: 254445

I recently bought a copy of EasyDraw 2.0 and I have some questions about
GDOS and Fonts for this package.

GDOS --> EasyDraw comes with version 1.1. Is this the most recent version?
Am I allowed to redistribute it, or must it stay with the
package (for instance, if I write something that uses GDOS can
I send this version out with it)? Is there some other source
for GDOS?

Fonts --> Does EasyDraw use normal GDOS fonts? The documentation reads like
this is true. If so, are there public domain fonts for publishing
systems which will work with EasyDraw? From what I have read,
Publishing Partner uses GDOS fonts, and there seems to be quite
a few PD fonts and a PD font editor available for it. These
should then work okay for EasyDraw, true?

Thanks in advance for any help you can offer.

From article <914@xn.LL.MIT.EDU>, by singer@XN.LL.MIT.EDU (Matthew R. Singer):

> Another amusing issue:

> I find it truely fascinating all this discussion about David Beckmeyer
> releasing RTX into the public domain. I can't believe how few people
> even knew it existed. They want it free, but are willing to pay a
> small amount for the docs. Well I have news for you all, its never
> NEVER been that cost prohibitive. All of 69.95 list and its been around
> for about 2 years... How can you expect him to support it for less?

My take on this is a little different. I've known about RTX for about
as long it's been around. I even bought the original (?) version of
the MT C-shell.

My problem with RTX was why write software for it if only people who
had RTX (a very small group) could run it? If DavidB makes RTX (the
runtime module...) free, then he might see more widespread _use_ of
RTX. With a critical mass of users his sales of documentation (?)
might well bring in more dollars than he has seen so far.

It's a gamble, but probably a good one.

You could draw analogies from the histories of Unix and the UCSD
P-system. The P-system spread very rapidly when it was cheap, and I
understand it brought in a surprising amount for money for UCSD. Then
they sold it to SoftTech, which charged large amounts of money, and put
in very little work (at Western Digital we did about the same amount of
work with two people part-time). Not surprisingly, the P-system
practically died.

1947. MJC, fixes to lib.c (1.2)

Newsgroup: comp.sys.atari.st
Date: 1988-02-23 00:35:39 UTC
From: egisin@watmath.waterloo.edu
Message-ID: <17054@watmath.waterloo.edu>
Source record: 254447

Here is some information I got in response to my recent article
on bugs in MJC version 1.2.

Version 2.0 is supposed to be released in a few months.
Most of the bugs I mentioned will be fixed, and it will have floating point.
Someone mentioned version 1.4, which suggests version 1.3 is available.
Since Mark Johnson can't post to Usenet, could someone with access
to Compuserve or Genie watch for new versions and post them to Usenet?

Mark Johnson's home address has changed since 1.2 was released,
here is the new address:
Mark A. Johnson
5315 Holmes Place
Boulder, CO 80303

I looked at the changes I've made to lib.c, they are numerous.
So I am posting two sets of context diffs,
the first including the more important changes,
the second including all changes.

Here is the first set. The only change are fixes to stdio.
The original only implemented binary mode for files opened with
stdio, and text more is much more useful.
So I changed things to use text mode, but the old behaviour
can be restored by undefining TEXT_MODE.

I don't know if Mark has implemented these modes
with the "b" and "t" options in the mode argument of fopen --
they are very important in MS-DOS enviroments (ANSI C adopts it).

If anyone wants to know more about Copyrights and software law, publishing, etc, pick up a copy of "Legal Care For Your Software", available at most B. Dalton Booksellers. It's up to date and has everything you'll need.

John

1949. Three questions.

Newsgroup: comp.sys.atari.st
Date: 1988-02-23 03:12:17 UTC
From: juancho@dgp.toronto.edu
Message-ID: <1988Feb22.221218.13780@jarvis.csri.toronto.edu>
Source record: 254449

I have three questions that people out there might have
answers to.

1) I just finished porting a 12K line program from our unix
system to a 1040 using MWC 2.1.7. The system() calls simply print
no shell when the program is running under gulam. I know that
setting the SHELL environment variable to GULAM will fix that. The
problem is that other mark william tools seem to be able to run
shell commands with out the SHELL variable being set, and if the
environment variable is set then a new copy of the shell is started up
for each cc in a make.

2) How does a typical mwc tool know that it has been called
from a shell. When ever I use a tool it seems to assume that the
program was run from the desktop and I have to press return.

3) How reliable are the malloc() and free() functions
provided with MWC.

1950. status of minix port to the ST

Newsgroup: comp.sys.atari.st
Date: 1988-02-23 03:13:43 UTC
From: UD138985@NDSUVM1.BITNET
Message-ID: <607UD138985@NDSUVM1>
Source record: 254450
Cross-posted to: comp.sys.atari.st,comp.os.minix

What is the current status of the Minix port to the ST, ie when is it going to be compleated? Also, I would like to know exactly who owns the rights to Minix. Does a company have a copyright on it and if so, who? Or is it shareware/freeware user supported stuff?

Thanks in advance for any replies.

Bob

Ok, here are the much sought after (by me anyway) addresses for the
mouse on the Mega.

Simply, the old addresses pluss 96 (decimal) , or $60.
That is, now on the Mega, you use, $2740, or 10048 (decimal)
I know the 10048 is right, but just converted the hex in my head
I hope it's right.

I found a few other addresses were plus 90 (decimal).

Some are plus 70 (deciaml).

If anyone is looking for a specific one, maybe I can help.

Drop me a line.

BTW, I have a non-Mega version of Arkanoid, and would like to get it
to run on my Mega, but I figure there must be more to it than just
the mouse addr changes, because it locks up solid before the game
reallt gets anywhere. If it was just the mouse addrs, wouldn't it just
not play? or something?

I'll mess with it and post any positive results.

thanks for your time,
Anthony Paul

In article <2069@polya.STANFORD.EDU> rwilson@polya.UUCP (Randy Wilson) writes:
>It may not be standard ASCII, but on the Mac, option-g gives a copyright
>sign in most fonts. Wouldn't this do the job?

It would do the job IF and ONLY IF you are sure that the document which you wish to protect by copyright will be displayed ONLY on another MAC or some other computer using the same code-to-character mapping for non-standard characters.

Since it is non-standard, it will not even look remotely like a "c in a circle" on most terminals/printers, and thus would not "do the job".

One interesting question is this, however: As has been stated, a "c in parentheses" is not a valid legal substitute for a "c in a circle".

Thus, " (c) 1987 by John Doe " is not a valid copyright notice.

However, since the notation "Copyright 1986 by John Doe" is valid, does the presence of "c in parentheses" between the word "Copyright" and the year REALLY invalidate the copyright notice?

After all, all that is required (the word "Copyright" and the year) IS PRESENT, there's just a bit extra.

Anyone care to comment?

> to find a resizeable and reset survivable ram disk.
> At least tell me why it's hard to do. I got no response
> to an earily inquiry except for requests to pass any
> information along.

Actually, this is one of those things I've had on the "what to do if I ever have enough free time for programming" list. But I was just pondering the question last week, and here are a couple of reasons that it is hard and quite likely impossible (and of course I'm open to corrections):

o If you wanted a reset-proof ramdisk, somehow you'd have to find a way to make TOS think that its physical memory size was changing on the fly -- at least, that's the way "eternal" does it. The "eternal" ram-disk changes the top-of- memory pointer and then performs a warm boot. I don't know if you can avoid the need for a reset when you want to set a new top-of-ram value. (In fact, I'm not entirely sure why it's necessary. Why doesn't "eternal" just do a big Malloc() once when it is run from the auto folder?)

o The main problem is with the Malloc() system routine. Its bugs are notorious, but in short, there is a fixed limit on the number of Malloc's any one application can perform. In fact, I once caught a message on Compuserve claiming that even if you're just doing something like:

```
while (1) {
buf = Malloc(size);
Mfree(buf);
}
```

then it _still_ stops giving you memory after a while. (I'd like someone to confirm this).

At any rate, those are the two obstacles that come to my mind. Maybe with the new TOS, the Malloc problem will be fixed. But if you were to just dynamically Malloc sectors as they were needed, I don't think you can make it resettable, since TOS will zero out all of its ram when you reboot.

I agree with Sean. Any dork who does that to a program and then has
the unmitigated gall to call it "shareware" makes one reconsider the relative
merits of The Kent Team, Red Sector, and SCA, virus not withstanding.

The proper term is "demo copy". Shareware implies a non-enforced
request for donations, *NOT* a demand for money. A "demo copy", on the
other hand, is understood to be a "limited" or "disabled" version. Good
examples of this are file transfer programs replacing every other packet with
the words "Buy this software.... you are using a demo copy.... Buy this ..."
and so on. There are some applications where a limitation is not normally a
possibility; a delay is a good alternative, but it makes the thing a *DEMO*
copy.

> The fact is, shareware licenses are unenforceable. People know
> they're not going to get caught, so legal threats don't bother them.
> They aren't made to feel guilty by whining pleas for money.

Or any pleas for money. Over 54% of all software used in business
is kyped. Hence the "Software Publishers Association" on the walls of the
room I am currently in, where every decent programmer KNOWS that a picture
of a CRAY or a UNIX -- LIVE FREE OR DIE poster belongs. Still, I make my
money from writing software, and I can see the authors' intent, if not the
method he used to impliment it.

> Shareware is a noble but stupid idea. It's based on a flawed view of
> users. It's almost never worked, and I'm pretty certain that it
> never will.

I recently (well, last comdex) met the guy who wrote PC-WRITE...
he's making gobs of money, so I don't believe the above statement to be true.
He said "I don't sell software... software's all up here [picture hand waving
in a circular motion, just above the head] ...I sell manuals and support".
Works for him. He had 8 people in shipping, last I heard.

> If I had a product that I wanted to sell, I'd try to market it
> through one of the major vendors, or I'd buy 2x3" ad in Amazing
> Computing or Amigaworld and take my chances.

You would be. From experience, it takes 6 months in a row for an ad
to provide a reasonable amount of draw. You have to wait for the user to want
or need the service/product you offer. He will go back to the magazine he saw
your ad in and look through it. If it isn't in the first one he picked up, you
are instantly a fly-by-night company and he goes elsewhere.

> If I wanted people to have the program for free, I'd copyright it and
> provide for free redistribution. No point in pretending that users are
> something they are not, and no point in looking forward to money that
> I'm not going to get.

I don't agree with your sentiment, but I welcome any software you
want to send me free (o|-).

I have to say that PC Ditto is worth the money...It runs just about everything. The only programs I have not been able to run using PC Ditto are some terminal emulation things like Pibterm. There are only two problems with Pc Ditto. The first is that it is slow on many things. However, interfacing with, say, DBASE III+ is fast enough. Using Procomm at 1200 baud is fine. Compiling and editing with Turbo Pascal is easy. However, some things are too slow to be useful. My biggest problem is that PC Scheme, the second most important IBM stuff to me, is in this category. My guess is that PC Scheme runs at about 5 percent of IBM PC speed. The editor cannot be used at all because of slowness. I am now testing PC TeX, the most important IBM stuff I have. By the end of the week I should know whether that is useful. The second problem is that PC Ditto, as far as I know, still has not produced a version for black and white monitors.

There is at least one alternative that should be available any day now. That is a hardware emulator from Monarch (Pheonix Az, I believe). This sticks on the back of your 1040 or 520 (all ports are still available, however), has 4.77 Mhz and 8.0Mhz clocks, and uses the ST memory only (it was originally reported that it had its own 512k worth of memory). Price: not fixed but expected to be in the $350 ballpark. I recently heard it was awaiting FCC approval. I will probably have to get this in order to run Scheme (unless an Atari version shows up).

Sorry, Keith, I don't know the answer,
but your question does raise another.

What is it that is new about this printer?
Ink jet printers have been around for some time, now.

But this is the first that I have heard them called "laser quality".
Which came first: laser printers or ink jet printers?

Does anyone know how to startup a ".PRG" Gem program from a ".TTP" program.
I can get the program to load and run but the mouse is not active.
The pointer is displayed and moves with the mouse but the buttons do not
respond.

The ".PRG" program executes correctly when run from the desktop and the ".TTP"
program will run other ".TTP" and ".TOS" programs with out problems.

Please email - I'll summarise.

While I cannot answer all of your questions, I can answer a few...

>(3) Is pc-ditto a worthwhile product?

Yes, pc-ditto is a terriffic product. While it is not extremely fast,
it does get the job done and opens up the owner to an avalanche of
public domain software or commercial s/w. The only problem I have
had so far is that it is slow with games.

>(4) Would it be practical to run an MS-DOS DB package on the ST using
> pc-ditto?

Yes, I have used dBase III+ with pc-ditto on my ST. It's functional
enough. It is kind of eerie seeing the IBM-pc font on the screen all
the while typing away at the ST.

I really do not notice the speed in dBase III+, except when typing
at the dot prompt. Otherwise (with Assist and the Applications Generator)
it seems just as fast as the IBM.

Good Luck!

We here at B.S.U. also experienced this problem, to say that we were a tad miffed is an understatement!!! We were all (approx. 10) wanting to dump our 8-bit Atari's and upgrade to the 520ST. My friend called, and after the "oops, thats a SLIGHT missprint" was given an itemized price list for his equipment, about $169 for his 800,850 interface,Percom drive and acoustic modem.... How generous.... from now on, we plan only to (try) to buy any/all Atari products face to face with a dealer.. though, the closest (not cheapest) is about 45-50 minutes away from where we all live! So, it again proves what my father always told me, "Don't believe everything you read, till you find out the facts from the 'horses mouth'"

A very disgruntled mail order attempter,

Copyright notice or no copyright notice, in my experience it's very
difficult to enforce outside the US and Canada.

There was a company in Germany that started to produce MT C-Shell with
their own manual, diskettes, and packaging. German authorities informed
me that this is perfectly *legal* in Germany, becuase you can't copyright
anything but "works of art"; and software isn't in this category.

The only illegal act would be if they were claiming they were selling
"original" factory goods. As long as they say they are selling copies,
it's legal in Germany. Even if they are breaking the law, all we could
do is attempt to get a court order to force them to stop selling.

The best solution turned out to be getting a real legit. distributor
in Germany; and let the competition of a supported product for less
money shut them down (which it did, I think). I don't know if the
legal issues above are "correct", but that's what happened to us.

There are versions of tar and untar posted on GENIE. They claim to be
compatible with Unix tar, but I have not been able to verify this.

Also Beckemeyer Development sells a hard disk backup utility that can do
volume backups to floppy.

Every time I've called one of these places advertising ST hardware
at unbelievable prices they have said:

1) "It was a mis-print"
2) "We changed our price"

And then they quote a more "standard" discounted price. No big
savings over the local computer store. I don't know how these
places stay in business.

1970. WordPerfect enhancement / mini-Review

Newsgroup: comp.sys.atari.st
Date: 1988-02-23 16:44:26 UTC
From: c162-br@zooey.Berkeley.EDU
Message-ID: <957@pasteur.Berkeley.Edu>
Source record: 254267

Well, it's the first Safety-Seal (mini) Review of this semester,
and I'm happy to say it's an optimistic one. This is about Word Perfect,
and my experiences with their bug-fixes.

After waiting patiently for a bug-fix to arrive, I finally called
WP Corp., and talked to a nice woman told me that I wanted the Jan. 8
version of WP. I then got transferred to Customer support, where a woman
told me that I didn't want that version, but the Jan. 29 version, and then
transferred me to the Orders department. Two days later, all six disks
of the new version arrived by Federal Express.
The new Word Perfect is a slightly bigger program, and behaves
differently in several respects:

It now uses separate SYS files, depending on whether it's run on
color or mono systems.

The cursor key repeat rate has been slowed down (ala 1st Word) so
that you can't over-scroll your text. It's a bit too
slow for my taste, though, as I had no trouble with the
previous version's scrolling.

The window sliders behave correctly now, and are almost always
the right size, too.

When you have a menu popped down, you can't still move the cursor
around and type text (the old Oct. 1, 1987 version had
this bug).

WP now allows a default document directory, so it won't keep
asking you for the directory name when you use its
own file selector.

WP now seems to give up all the memory it takes. Previously,
some exits would leave about 100K locked away.

It doesn't seem to lock up or crash as often. Actually, I haven't
had any problems with at all, but one of my roommates has
hung it up once.

The version number (date and all) used to be only in the Help
screen. It is now also in the About WP... dialog box.

It now comes with CONVERT.PRG, which can convert 1st Word,
Word Writer, and ST Writer files into WP format. No
reason not to switch now!

Aside from these, the subsidiary program for the printer drivers has been
changed, too (well, its file size is different). Some more printer drivers

have been added to the data file, including one for Atari's laser printer.

On the bad side, it seems to take about two seconds more to run from the hard disk; after the initial screen pops up, it takes two seconds before you can do anything. It seems to be accessing the hard disk, but I don't know why; the older version didn't seem to do that.

Overall, I'm impressed. Their initial documentation seemed to suggest that they would send out bug-fixes to us when they were finished, but I had to call for them; of course, a toll-free number plus the quick delivery dispels any qualms I might have had. Another thing to remember, for some of you, is that I've gone from the Oct. 1 version to the Jan. 29. Some of these fixes may have been in effect in earlier bug-fixes, but I don't know that.

Last thing...

I had the opportunity to play a new game called Star Trek: The Rebel Universe. I have not played it extensively, but I think it's a very good game. There is a lot of detail, quite a few solar systems to explore, and some very nice digitized sounds, too. Of course, since I keep getting destroyed (I'm a terrible player), I can't say if the ending is any good. Anyways, I recommend checking it out at the store if you have a chance.

> ================================================== -- Cameo

No, Publishing Partner does NOT use GDOS, and thank GOD for that.
Deron (author of PP) uses his own scheme for the screen and printer fonts
and has done a very good job. In PP, one can have say 6 different fonts
loaded, and each font can be used from around 5 pt size to 144 pt size.
All these take up about 30 K of RAM only. Try that with GDOS (which
practically requires a different file to be loaded for each size) and you
will need a Mega64 ST just to load all these fonts!!

The new PP Professional may be using an even better font scheme (and the
old ones are supposedly upward compatible). Since a few people have asked
me, the upgrade from Publishing Partner 1.?? to Publishing Partner Pro
is $55 (include handling/shipping)

1972. Laser C

Newsgroup: comp.sys.atari.st
Date: 1988-02-23 18:06:04 UTC
From: wolenty@inuxj.UUCP
Message-ID: <321@inuxj.UUCP>
Source record: 254269

Well, I got my new Laser C update yesterday! Unfortunately the
Utilities disk was unreadable - sending it back for replacement.
While program space may be free of 32K segmentation limits, it
appears this limit still exists for initialized data. I have
a program that initializes several large arrays - I used to get
a segmentation error message of some type. Now I get an exception
message that says CCOM.TTP is out of memory. A quick check of free
RAM shows more than 512K avaiable. Seems like an odd error message.
Can anyone from Megamax comment??

>After all, all that is required (the word "Copyright" and the year) IS PRESENT,
>there's just a bit extra.

I would put my money on notices of the type:

(c) Copyright 1988 Jim Frost All Rights Reserved

as being legal for two reasons. First, it satisfies the requirements
of the copyright law, and second, your uSoft linker displays this when
you run it. It seems likely that uSoft's lawyers know what they're
doing.

Whether or not

Copyright (c) 1988 Jim Frost All Rights Reserved

is legal would be open to interpretation, but again the law only
states that the word "Copyright" (or the abbr. or \(co), the year, and
the name be present. Hence

Copyright 1988 by Jim Frost All Rights Reserved

should also be valid (this is another common one and I believe that it
is valid). In both of these cases, they fulfill the copyright law to
the letter.

Does anyone have a definitive answer? Is it legal to place other
words or symbols in the copyright notice so long as the notice is
still obvious?

> shel_write() also seems to suffer from this same problem. Is there any
> good solution, short of hacking-into the OS?

I think you hit on the solution without knowing it: closing their windows doesn't pay, but you can SEND THEM the AC_CLOSE message (I think). Check the message library for "send a process a message" and check the application library for "get ap_id for an accessory" (I don't really know that much AES). Then send the accessory the close message. Sending it wind_close is usually enough, since (like the Control Panel) clicking "close" in the window usually shuts down the accessory as well.

Failing that, you could try the opposite of app_init -- I forget its name -- because I think it's that call which closes accessories, not Pterm(). Pterm() doesn't know a thing about accessories, or AES, or anything at that level. So try app_deinit before the Pexec and app_init after it. (Remember that your window handles might be different after the new init... They probably won't be, but write your code as though they might be.)

Like I said, I don't know much about AES -- don't take this as Gospel.

1975. Help with PC Ditto

Newsgroup: comp.sys.atari.st
Date: 1988-02-23 20:20:19 UTC
From: Desaulniers.PA@XEROX.COM
Message-ID: <880223-122027-1148@Xerox>
Source record: 254272

I have PC Ditto version 3.0 (the newest version) and I am programming in Pascal with Turbo Pascal. My program needs to do two things that I am having problems with. First, it must read data from a input data file as opposed to the standard input device (i.e. the keyboard). Secondly it must output to an output file as opposed to the standard output device (i.e. the screen). I will then send the output file to the printer so I have a hardcopy of prog's execution.

My problem is that when I compile prog as a .com file in Turbo and then execute it from DOS (i.e. A> prog) and try to use standard DOS I/O redirection (i.e. A>prog < input.dat or A>prog > prog.out) it executes the program but does not access either input or output files.

Does anyone know if PC Ditto does I/O redirection via DOS? Does anyone know how to do this some other way using PC Ditto?

Peter

From: Thomas_E_Zerucha@cup.portal.com
Message-ID: <3443@cup.portal.com>
Source record: 254274

Reset-proofing is straightforward, but requires a warmstart, since the
standard technique is to alter PHYSTOP and leave something at phystop+n
to indicate there is a ramdisk actually there, then reinstall the vectors
the second time through the auto folder. But then resizing becomes difficult
without another warmstart, but otherwise would simply involve insuring that
the latter region of the ramdisk is not being used, then adjusting the
free space byte in the boot sector, moving it (and changing phystop to reflect
the move - and the move would have to be bottom up), then warmstarting again.

Date: 1988-02-24 02:05:56 UTC
From: Thomas_E_Zerucha@cup.portal.com
Message-ID: <3447@cup.portal.com>
Source record: 254279

PKARC/PKXARC are (almost) unique to the IBM PC. ARC 5.12 is the latest rev
as far as packing formats, but ARC 5.20 (on PCs) could create self-unpacking
archives (a .exe file that unarced itself).
I have done enough porting to have created a simple unarc which handled
squashed files (PKARCed - using 14 bit LZ without repeat packing) for the ST.
But PKXarc runs under PC Ditto, so you can use that as well.

1983. Lazer C Shipping & Jan 29 version of WordPerfect

Newsgroup: comp.sys.atari.st
Date: 1988-02-24 02:19:16 UTC
From: parora@gpu.utcs.toronto.edu
Message-ID: <1988Feb23.211916.19791@gpu.utcs.toronto.edu>
Source record: 254280

I called Megamax this morning and was told that Lazer C was being shipped as of last weekend. Good news. I am eager to get it since I mistakenly sent in my utilities disk without making a backup :-{. Perhaps Michel can confirm this.

Also good news for WP users. I have recieved the Jan 29 version of WP and it is very much improved over the previous ones. One annoying bug seems to be when you try to back up past the beginning of the file or past the end of file, the cursor jumps back into the file. i.e. if you are pressing LEFT ARROW on the first character of the file, the cursor jumps into the file by about 5-10 chars. It almost seems like it thinks that it is in reveal codes and positions the cursor past all the codes??
Overall though I think that the revision has helped immensely. I also understand the wp_print is to be updated in the near future.

It's feels nice to be able to write about good news once in a while.

I vote for 2. 3 is bad because you have to wade your way through too much stuff
just to find programs; also, there is no separation of sources and binaries. 1
is bad because it doesn't work. Why burden one guy with so much work? Why rely
on one guy's time (and machine) to get PD programs through to everyone?

2 is great. I can just picture all that code coming through... No more bottlenecks.

You know, after reading Matt Singer bash Atari's unprofessionalism,
I'm beginning to wonder: How many Atari software developers out here in
netland have *Major* gripes with how Atari supports the ST?

I'm not a professional, nothing fancy, just a "Joe User" who thinks my
1040 ST is one of the best buys out there (just like the 800, when I
bought it many many years ago)...And I'm getting a little worried. Are
all you guys gonna give up on Atari, and I'll be stuck with a dead machine?
Is anyone in any decent PR/administrative position at Atari LISTENING
to us? Whaddabout Jack tramiel, the man who nobody ever gets to see in
person? DOES HE EVEN CARE???

(Okay, I might be going overboard, but I'm interested)

2001. Re: ETRNL2 and new roms

Newsgroup: comp.sys.atari.st
Date: 1988-02-24 13:44:00 UTC
From: franco@iuvax.cs.indiana.edu
Message-ID: <36500035@iuvax>
Source record: 254298

I can probably fix ETRNL2 to work with the new ROMS but I need
the following information to do so:

1. What are the locations of phystop, _memtop, drive_bits, _membot,
hdv_BPB, hdv_rw, hdv_mediach

2. Have any changes been made to _kbshift ($B of TRAP $D)? If so,
what? Is the bit vector the same?

If I get this info I will try to assemble a new ETRNL2 and send it to
people to test.

Bonus:
The new ETRNL2 will have a bug fixed: the first version did not
clear the FAT and Root Directory when resizing so resizing downward
according to the instructions given sometimes causes strange files
and folders to appear. This is fixed in all but the first version
I posted and the new ETRNL2 will behave properly in this regard as
well.

I put in a real media change option - this was a result of a program
I wrote to dump a series of floppies to the RAMDISK on bootup. I
found that folders were unknown to the system without a media change
on the "hard-drive" (so here seems to be another case for having
hard disk media changes). This media change option, by the way,
can probably be used for hard-drives as well as the ramdisk without
modification (I am not sure about the modification being unnecessary
since I do not have the code in front of me). However, to use it,
one must force the media change from software. Thus, to do the
media change one must actually run a program to set a bit in the
ramdisk drivers (of course this can be done from a program for
checking free space etc. so the penalty won't look so bad).

Please send system info requested above to:

franco@iuvax.cs.indiana.edu

Please respond only if you really know the answers to the questions.

I've seen this behavior before, and I think you are correct in saying that it seems like the cursor is positioned before all codes. But this is correct behavior as described in the manual. You ARE supposed to be able to position the cursor before all codes by using the arrow keys only.

So anyway you can get this "strange" behavior if you have some margin codes in your document.

2003. Re: fsel_input

Newsgroup: comp.sys.atari.st
Date: 1988-02-24 14:26:00 UTC
From: SCHOMAKE@HNYKUN53.BITNET
Message-ID: <8802250623.AA17637@ucbvax.Berkeley.EDU>
Source record: 254203

[]
About the recent requests about fsel_input. Wouldn't it be nice to re-design
the selecting of files, instead of modifying the existing fsel_input?
In my opinion, opening files should be done by means of the standard
double-clicking procedure on the desktop. The scenario:

1) Double-click on a .PRG file icon and the program starts,
2) but the desktop stays intact containing all windows. Only, the menu_bar
changes into a program title bar, now containing a prompt, (e.g.):

```
-------------------------------------------------------------------------
| MYPROGR Input file? ________.___ |
-------------------------------------------------------------------------
| --- --- --- --- --- --- --- --- --- --- |
| | | | | | | | | | | | | | | | | | | |
| |fil| |dta| |etc| |foo| | | | | | | | | | | |
| --- --- --- --- --- --- --- --- --- --- |
| |
```

After a single click on a file icon, the selected file name appears in
the bar, clearly visible in system font. D-clicking on a file opens it.
Characters typed from the keyboard appear in the bar if manual input
is preferred by the user. All Gem desktop manipulations (apart from the
drop-down menu's) such as resizing, opening windows etc. are possible.
3) This is repeated for all required input and output files, the prompt
changing accordingly.
4) The desktop dissappears and the program starts with its own desktop and
menu_bar.
5) Intermediate file saving etc. is handled likewise: the Gem desktop
pops up "from under", to give the user a broad overview and desktop
control as opposed to the limited fsel_input dialog box.

A similar approach could be used in place of the .TTP dialog box,
e.g., the user types "<" and selects an input file, types " >" and selects
an output file, possibly followed by some typed options. Characters appear in
the program title bar, as above.

```
Can anyone tell me the semantics of the 'mode' arg to the OPEN, CREATE
and SEEK traps? I'm looking for enlightenment on how to do things like:

open an existing file for output, position to end
" " " " " " " " beginning
open existing file for bidirectional IO, position randomly
create new file for bidirectional IO...

ad nauseum. Thanks in advance for any info.
```

Date: 24 February 1988, 14:50:18 EST
From: Jim McCabe JEMCCABE at MTUS5
To: INFO-ATARI16 at SCORE.STANFORD.EDU
Subject: ST OmniRes & thanks to Allan

First of all I'd like to thank Allan Pratt for responding so quickly
to my posting about a problem I've been encountering with GEMDOS.
At least I know the problem isn't _my_ fault so I can stop pouring
over my code trying to find nonexistant errors. And at least the
bug is fixed in the new OS. (And now I also have a horses-mouth
disclaimer to put into the docs explaining that the problem insn't
a bug in my program! :)

Now, on to the real business...

I'm probably going to buy ST OmniRes from the E. Arthur Brown Company.
I remember reading a review of it in a past info-atari16 digest, but
can't seem to find it. Does anyone have anything good or bad to
say about this product? I'm particularly interested in the quality
of the fake color images on a mono screen and in the speed of the
emulation.

Thanks in advance!

>Does this sound reasonable? I would like to see this kind of thing
>become a standard, ...

If this is what everyone agrees to, I will do it. I never told MWC how to do ARGV=; they just did it, and so I went ahead and changed my programs to support it. I don't know if it ever reached you personally, but I and several other company reps. approached Atari for a "standard" way of doing this way before MWC came along, and collectively we were told (I quote from memory) "Atari won't make anything a standard; do it any way you want, but we won't necessarilly support it, and it may not be compatible with future Atari software and systems."

At that I did it one way, and then MWC came along with another way, and the rest is history.

Now at least MWC and Micro/MT C-Shell are all compatible. If the above approach is the new "official" standard, I will implement it; but not before I know it will be supportted.

Would it also work to compare argv[1] from the ARGV= and from the command tail, and if they differ, use the args from the command tail?

(This is not a flame on Alan. It's directed at Atari upper management BS).

Yes: it sounds like he used the unpublished, floating variable for the
keyboard shift state, rather than the BIOS call which gives the same
information.

I can understand using the OS variable when it's time-critical, like
in the main loop of a game, but why not use the BIOS call when it's
just a one-shot? Beats me.

>
>If the bottleneck is in moderation, why not just make comp.binaries.atari.st
>unmoderated and post binaries there?

There are advantages to moderation. You don't get 50 people who all have a new version of <spiffy 100K program> all posting it at once; with propagation delays you might post 7 or 8 days after someone else does without seeing their posting.

Also if you know your program will not be posted for several days after you send it, it gives you the chance to add in new features, fix bugs and send off the newer version _before_ the net gets cluttered with the first one.

And since the moderator is supposed to test things before passing them on, you are assured that at least one person has successfully unarced / uudecoded a binary before it's put into general distribution. Ever download > 200K and find out that it didn't work because someone's mailer garbled line 1000 of the uuencoded file? I have, I'd rather have things like this happen to a moderator :-) .

2019. Laser C

Newsgroup: comp.sys.atari.st
Date: 1988-02-24 22:09:27 UTC
From: rob@hhb.UUCP
Message-ID: <713@hhb.UUCP>
Source record: 254204

[This space intentionally not blank.]

Some info:
Yesterday (2/23) I found in my mailbox the long-awaited upgrade to Megamax's compiler, Laser C. The package contained three SS disks and a small sheaf of excerpts from the not-yet-ready manual. An accompanying letter explained that due to problems with their printing service, Megamax won't be able to ship the manual until 2/29 but it will be released "as soon as is humanly possible."

A question:
Does anyone know if Data Pacific's Translator One allows one to run copy-protected Mac software "out of the box?" Specifically, I'm wondering if 'Sargon III' and/or Mindscape's 'Uninvited' work.

A short product review:
If you are tied to a monochrome system don't bother buying MichTron's 'Cards' software package. The user interface is woefully primitive. They don't even use grays to distinguish between black and red cards, which makes playing solitaire an exercise in frustration.
I've seen better PD card games (albeit for the Mac).

I'm not the only one who has problems with samsung memory. Ask around.
Why do you think these are the cheapest on the market - because they
bought the masks to older technology parts. I'd rather have NEC, or
hitachi stuff in my machine. By the way - why did the upgrade with
samsung parts fail ?
(I have nothing against Korean made parts - I just find japanese and american
more reliable !)

The reason for putting 68 ohm resistors on the CAS lines is due to the lack of an efficient ground plane on the ST. The resistors are there to reduce ringing on these lines which causes the memory to be "double-clocked" - ie. think valid data is there when it isn't. A better idea would have been to actively terminate these lines, but a series resistor is cheaper and seems to work. (note: this is a reason many 4 meg add on boards don't work when fully loaded on the ST - they are too noisy and CAS gets confused)

me too. Seems like they got a bad batch of disks let out...i sent
mine back and they will be sending me back a new utilities disk.

The environment is great! I like the environment, seems better than MWC.
Tho' I will reserve judgement until i get my docs and utilities.
Laser has a nice make, shell, and windowing environment.

2025. Atari 1040ST for sale

Newsgroup: comp.sys.atari.st
Date: 1988-02-25 04:21:00 UTC
From: minow@thundr.dec.com
Message-ID: <8802250120.AA23604@decwrl.dec.com>
Source record: 254225

My apologies for the wide distribution, but my mailer cannot limit postings.
For sale: Current prices
Atari 1040 STf, one year old. $899
Monochrome SM124 monitor, 1MB memory, 1 disk
"Japanese" trackball
Atari software: 1st Word, Basic, Logo
Timesaver battery backup clock $ 40
Mark Williams C (version 2) $162
Athena Draw (CAD system) $ 95
Flight Simulator game $ 35
Balance of Power game $ 40
Abacus Internals and Gem manuals $ 40
Various PD utilities and games

Above, sold as a unit, for $975

Panasonic KX-P1080i printer (Epsom compatible) $175 ($230 new)
(includes connecting cable).
Supra 30MB SCSI-compatible hard disk $800 ($899 new)

Everything is in perfect working order. I'll deliver and set it up in the Boston area. Note that new Atari's lack bundled software (not that the software is all that good) and the SM124 monitor and Japanese trackball are rumored by net postings to be better quality than the currently-distributed hardware. The Atari makes a superb terminal (I'm using it now), so I'm in no rush to sell.

2026. Laser C

Newsgroup: comp.sys.atari.st
Date: 1988-02-25 05:18:31 UTC
From: ST901922@BROWNVM.BITNET
Message-ID: <8802250639.AA17856@ucbvax.Berkeley.EDU>
Source record: 254226

LASER C HAS ARRIVED!

I unexpectedly received a package from Megamax yesterday (2/23) containing three disks comprising the upgrade of Megamax C, some interim docs (look like xerox of manual, and provide a glimpse of what looks like a GREAT manual!!!), and a note of apology from the company. They say the full docs will arrive soon after 2/29/88.

I guess this info will be of more use to those who might be contemplating buying Laser C, because I assume that if I got the software, so did the rest of the Megamax owners who will read this! Anyway, the package looks real nice. The editor and shell are now combined, and the shell has been GREATLY enhanced. It contains UNIX-style environment-string management (maybe something like MWC, from what I have gathered by reading this newsgroup's postings), a sort of mini-dos shell (very well done), a dynamic disk cache that, from my already heavy usage, ahs proven to be an amazing piece of work!. It also manages a set of user-selectable tools, which are kept RAM-resident. That's right! When you load the shell, you can tell it to load the compiler, linker, make-interpreter, and any other utilities you want. Then compilations are almost INSTANTANEOUS. You don't even have the overhead of loading from a ram disk!
The disk cache routines seem to be so efficient that you seriously do not need a ram disk at all. I used to have a 512k ram disk for Megamax development at all times. No more! The editor has been enhanced; the scrolling is faster than anything I have ever seen for the ST, even faster than most Mac editors and wp's I have seen. (The only problem is that they wrote their own windowing routines and occasionally there are very minor glitches with them.)
The shell will also trap 68000 exceptions and provide you with a symbolic traceback if you asked for a symbol table at link time. The program nm.ttp has been added to the package to read a symbol table.
The ONLY thing missing is a source-level debugger. I have never used MWC, but I bet csd with Megamax C would be quite a combo. Seriouly, folks, the hello, world program compiles IN LESS THAN FIVE SECONDS with no ram disk or other tricks.
Sorry if I have rambled on but I am absolutely in love with this product! I KNEW that $200 was worth it!

DISCLAIMER: this is my first posting, so the disclaimer expressed herein is nonbinding.

2027. Books to learn by?

("Oh God, more bandwidth taken up by THAT idiot...")

Hi there. In the unlikely even that I'll ever get enough money to buy a
C compiler, can anyone recommend what book(s) I should get to learn about
Atari ST programming?

I'd like to know as much as I can about graphics/sound and disk structure
(yeah, another games-oriented screwball...Don't ya love us?); What books
should I get/avoid? Abacus' line of ST books seem interesting, but I've seen
them flamed/praised, and I'm not so sure.

I've also got a copy of Sybex's "Programmer's Guide to Gem". How applicable
is that material to the ST? What (major) discrepencies should I know about?

Please, go ahead and reply, e-mail or netmail...Flame me, heckle me,
something that resembles a reply.

Thanks in advance,

From: johan@nlgvax.UUCP
Message-ID: <214@nlgvax.UUCP>
Source record: 254228
Cross-posted to: comp.sys.atari.st,comp.os.minix

Two questions were asked about MINIX-ST recently on the net:
1)
>Will the C compiler generate executables larger than 64K? If not then its
>crippled and pretty useless in the ST world. On the other hand, if it is,
>then it seems that the IBM will rapidly fall behind as more and more Unix
>software is ported to the ST (but because of size can't be ported to the IBM).
Yes, the C compiler uses 32 bit addresses (and 16 bit ints), and can
generate large programs. You can run programs as large as physical
memory allows.
It is a good UNIX tradition to avoid large programs, although lately
this tradition seems to fade away.

2)
> What is the current status of the Minix port to the ST, ie when
>is it going to be compleated? Also, I would like to know exactly who
>owns the rights to Minix. Does a company have a copyright on it and
>if so, who? Or is it shareware/freeware user supported stuff?
MINIX-ST will be copyrighted by Prentice-Hall, like MINIX-PC. Expect
it to be available from Prentice-Hall late Spring (around June), if no
further obstacles are encountered.

I hope this answers most of the questions on MINIX-ST for the moment.

I agree with the fact that the American and Japanese parts are far superior, but you bluntly stated that the Samsung chips won't work. And they do!

The reason the upgrade failed was ram chip failure (of course!). Of course you aren't the only one who has had problems, why should I ask when it has happened to me?

I answered all the questions you asked before you asked them.

And NEC and Hitachi are among my least favorite of Japanese parts - I prefer Toshibas for Japanese and TI for American. But with the prices now, it's almost cheaper to get static ram.

2033. Megamax laser C

Newsgroup: comp.sys.atari.st
Date: 1988-02-25 19:46:39 UTC
From: mgr@pixar.UUCP
Message-ID: <1504@pixar.UUCP>
Source record: 254233

Well, Megamax's laser C came in the mail day before yesterday
and I spent a late night last night takeing her out for a spin.

So far, I'm delighted with what I've found, although I haven't
dug in very deep yet.

Laser C is a development environment, modelled more on the editor
than on the original Megamax shell. The editor functions are
basically the same as before but are lightning fast - giving an
even tighter feel to the mouse interface.

The big gain in speed, though comes from not having to exit the
editor to do a compile. Compiler and other printed output is displayed
in a GEM window. There's no need to re-open the file and find the
spot you're working on after each compile, link, debug, cycle - your
file is open and the cursor is right where you left it.

There are several new features I won't mention - lest I sound even
more like an advertisement. Suffice it to say Laser C is well worth
the $20 upgrade.

Caveats - I haven't used this new package for actual development yet,
and don't know whether my great mound of graphics and midi library
routines will carry over, so stay posted. Another problem: documentation
is very minimal, particularly for make, and this will hamper non-Unix types.

Re Mark Williams C - also an excellent product. I have version 2.0 and
use it where I'm concerned about Unix compatibility. My style of programming
meshes better with Megamax's quick compile times. In general I have been
recommending MWC for people who are interested in Unix familiarity, and MM
for performance oriented programmers who don't mind a few lumps in their
cream of wheat. MM and MWC have both improved recently, and I think my
recommendation will remain about the same.

If asking will help, I request that we not have a dose of compiler wars
over this - I once watched a potentially valuable developer's conference
go largely down the tubes due to bickering over MM versus MWC. Let's keep
it light and informative, please.

From: portal!cup.portal.com!Thomas_E_Zerucha@uunet.uu.net
Subject: Re: Atari 68030 computer?
To: info-atari16@score.stanford.edu

Thanks for the report on the 68030. I am wondering if there will be at least
a socket for a 68882 (if not the chip - or the 881) or some other support
for floating point. In this case I think I prefer to stick with the standard
882 instead of going custom.

Martin Wiedmeyer writes:
>
>This is the first I've heard of the Craft development package and STedi. If
>it's faster than Tempus, I'm really interested. Where can it be purchased?
>

I am surprised that knowledge of the Craft development package has not yet
made it out to usenet. While I was living in Holland I had the privilege
of being one of the beta testers of this package, and since then I have

come to depend on it. Since I like it so much, I will be glad to answer.

STedi is a very fast editor that was written specially for the ST. To say that it is faster than Tempus is perhaps missing the point. It is indeed faster than Tempus in many respects (for example the search/replace routine is a little faster but this can only really be seen on a file > 200K) and in a few aspects it is perhaps slower, although I am not sure. Both are so fast that the speed of the editor is no longer a factor. The important fact is that STedi is much much more powerful as an editor. Aside from all the regular features - search/replace, cut/paste, undo, etc. there are many non-standard features such as:

- 8 text buffers: switch between them at the stroke of one key.
- 10 learn buffers: record up to 100 keystrokes for replay
- complete key redefinitons: one key can be redefined to perform the action of one or more keystrokes, or even multiple keystrokes can be defined to perform the action of only one. This can be used to emulate another editor. I have seen an almost complete emulation of the Vax edt editor running.
- insertion of non-standard ASCII characters is easily done, via hex code. (combine this with key redefinitons ... - one beta tester configured STedi to type in Hebrew - complete with charcaters appearing in reverse order)
- "folds": you add a couple of lines in the program that are comments to the compiler but allow the editor to suppress all text between them at the stroke of a key, or a click of the mouse. This allows organization of the program in logical units which can be 'opened' and 'closed', sort of like an outlining feature in a word processor, but is done all in ASCII.
- cut/paste can be used only in a certain range, or just in specific columns, as well as can search and replace.
- automatic wordwrap and auto-indentation features
- edit hex code directly and write it back out to disk
- execute external programs (compile etc.) from within the editor.
- alternate fonts (fixed width only)
- save configuration (key redefinitions, fonts, numerous settings I haven't mentioned) to a file to be read at startup.
- find matching parenthesis command
- find next occurrence of present 'word'
- etc.

This is only the beginning. So you see STedi is not really even in the same class as Tempus. I should add that STedi does not use the GEM windows/menus interface although this is actually an advantage in my opinion, the way the program is written. This allows full 80 column (in fact a line can have up to 255 characters with horizontal scrolling) by 24 line editing and more if a smaller font is used, and no compromise is made with ease of use. The mouse can be used for moving the cursor, scrolling, opening and closing folds, etc. as well as for reading and writing through the file selector, cutting and pasting etc. A menu bar appears at the bottom of the screen in contrasting color (much in appearance as Uniterm), which is also used for commands. <Esc> brings the cursor there to enter commands. The status of certain modes (insert/overwrite mode, and the like) the name of the file being edited, and the current line number are printed there. Also messages appear there

depending on the circumstances. This is all sort of like EVE on the Vax.

Perhaps the most outstanding thing about the editor is the paying attention to detail. For example, if you exit (one keystroke for save current buffer and exit, another for just exit) only if something is unsaved are you queried. No clicking away of unnecessary dialogue boxes, etc. (as with many of our unfavorite editors and word processors) Or when you paste something in, and realize you don't want it there, the editor is already configured to recut it out. Such time saving features can be invaluable to the programmer. All in all, aside from perhaps the LSE editor on the Vax along with some personal touches (compiled TPU additions), I have never seen such a powerful and at the same time user friendly editor as STedi, on a main frame or a micro.

STedi is being marketed as part of the Craft development package by Commedia in Amsterdam:

COMMEDIA
P.O. Box 6409
1005 EK Amsterdam, The Netherlands

The other side of the package is a Unix-like shell called the GPshell, which is also an extemely nice piece of software. Besides providing Unix replacements for all GEMDOS functions, and with standar unix features such as aliasing, history, wildcarding, redirection, pipes, etc. there are a number of non-standard features also such as the possibility to edit previous commands (more like VMS), if you start typing a file name and then press <Esc> the filename is completed for you insofar as it is unique, and a ramdisk and print spooler are included that can be created or destroyed at will from the shell. As the original question was about STedi I won't go on about the shell except to say that the two work very well together. If the shell is present, STedi can execute any shell commands besides external programs. We bought our copies of Craft (at FSU) for around $200 U.S. although the price might have gone up due to the exchange rate.

If this sounds like an advertisement, it should, because I am one satisfied user. I would like to see such an excellent product succeed. (Disclaimer:) However, I have no relation to Commedia whatsoever.

][

A while ago a message was sent to Info-Atari16@Score.Stanford.EDU by a
certain Andrew with an e-mail address of
andrew%MARV%EENG.BRAD.AC.UK
on the subject of a new server for Atari ST software in the United
Kingdom. Said Andrew gave an e-mail address of said server, to wit:
server%MARV@uk.ac.bradford.eleceng
The reason I'm posting this to the world at large is that it has been
impossible to get e-mail through to either of the e-mail addresses
provided. Gateway mail to JANET via BITNET to the addresses provided
just bounces back to the sender as undelivered (and undeliverable).
It really is remarkable that we on the Continent can download and
upload stuff back and forth between UH-INFO@UHUPVM1.BITNET (the Houston
UACE server) or LISTSERV@CANADA01.BITNET (the PROG-A16 server) whereas
we can't access Great Britain!

So, please, Andrew, make yourself (and your server) more available to
us BITNET folks by telling us how to best reach you.

Demetrios N. Velis <u00311@hasara5.BITNET>
Dept. of Neurosurgery, Academic Hospital of the University of
Amsterdam, Amsterdam, The Netherlands.

2037. Re: Changes/fixes to OS

Newsgroup: comp.sys.atari.st
Date: 1988-02-25 21:04:19 UTC
From: good@atari.UUCP
Message-ID: <995@atari.UUCP>
Source record: 254237

Allan made a very important point in a recent posting, and that is that programmers for the ST, or any machine, MUST abide by the published rules when designing and writing software if they expect their code to run unaltered on future revisions.
One of the greatest problems any company has is maintaining compatibility. It's bad enough when a published, supported, interface forces a systems programmer (eg Allan Pratt) to make compromises in an enhancement or bug fix - that is the price paid for an open system. However, it is much MUCH worse when a good, desirable, improvement to systems software (TOS in the case of Atari) has to be removed or seriously reduced in impact just because some widely used software disobeys the rules and hits the OS directly.
I realise I have only been at Atari for about 6 weeks (it seems longer [:-)]) but this applies to ANY computer supplier. There is the constant worry that a major enhancement that would really improve the value of the product for well-behaved applications will cause others to fail. And, of course, the congratulations for the enhancements will be totally obliterated by the flames and flak from those whose pet programs no longer work.
Every feature of the forthcoming TOS, fix or enhancement, has to go through vigorous discussion of how it will affect existing users. This in itself adds to the development and test process considerably.
When a manufacturer releases software or firmware which is bundled with every system, he/she must stand by it. When an independent makes such a release, he/she can decide whether to provide total compatibility or to state certain restrictions on the product's use.
So PLEASE, keep to the rules and understand the impact not so doing has on the development process.
And we thank you for your support.

Roy J. Good
Product Development, Atari Corporation

Views expressed are my own. Atari may agree or disagree; they have the right.

> But why would you want to handle bombs any differently from ^C?
> (Besides, correct programs don't produce bombs! :-)

Well, if you're writing an interpreter for a programming language, you want ^C to interrupt the running interpreted program, but not the interpreter itself. On the other hand, you want a bomb to kill the interpreter.

2039. Re: Lazer C Shipping

Newsgroup: comp.sys.atari.st
Date: 1988-02-25 21:28:41 UTC
From: braner@batcomputer.tn.cornell.edu
Message-ID: <3861@batcomputer.tn.cornell.edu>
Source record: 254239

[]

I got the Laser C disks with about 20 pages of docs (photocopies of selected pages from the upcoming manual, apparently). They promised to ship the full manual "as soon as humanly possible". The system includes many new features such as a graphical shell with a multiwindow editor , including a "stdio" window, the ability to enter command lines from any window, and built-in tools like "cd", "rm" etc. The main parts of the system (compiler, linker, "grep", etc) may be configured to stay loaded in RAM (ready to run, NOT in a RAMdisk) and a disk cache is built in too. CPU exceptions are trapped and you get a message like "exception #2 (bus error) in program... probably safe not to reboot...". If you compile with the option for it, the exception handler will tell you which function the exception occured in, and which function called that one, etc. (There IS a provision for external debuggers.) More when I have time to actually try the thing...

George

About the mailing of the files containing MX2, the server in houston
has the uuencode/uudecode programs necessary to convert the arc files to text
so that they can be sent across the net. (bitnet server that is). Just encode
them and send me the files. Since you got mail to me before, you must
know what to do to send the encoded files to me.

I tried to send mail to you to tell you this instead of posting it,
but the mailer bounced back to me and I don't know how to get mail to you.

While your at it, how about posting MX2 on the server in houston so that
everyone can have it?

Thanks.

Bob

2044. Re: Atari no-support?

Newsgroup: comp.sys.atari.st
Date: 1988-02-26 00:49:04 UTC
From: Thomas_E_Zerucha@cup.portal.com
Message-ID: <3493@cup.portal.com>
Source record: 254244

Flame on:
I do have problems with Atari's support, or lack thereof. They aren't really advertising, and although they are at capacity, and a big hit in Europe, no one is going to hear about MY software unless I make a big effort myself to promote it. They recently did a MIDI ad and mentioned several companies and products - what about basic stuff?
I have found a wonderful place to get my ST and software from, who know their stuff and have a good selection - and they can't sell the Megas because of Atari's policy. Atari was almost the computer for the rest of the rest of us - but they are becoming Mac like in their stuffiness.
Flame off:
Atari is better in some ways - I could as an independent get the devkit for $300 - they don't require a financial sheet before you can get something from them. In terms of SOME technical support, they are better than most.
The ST is a very nice machine to work on because they did a lot of good design up front. I don't have to coax the ST to get something to work, it is fairly simple to do most things.
Flame on:
Are they going to really support the ST, or drop it in favor of the Abaq and the 68030 Unix Box. The Mac has been upgraded, but still maintains compatibility - will the ST?
Since the ST is dependent on third party software - as are most computers Atari should do something more to help us market the software - if in no other way, at least to advertise the capability of some of the more major packages. Most people don't realize the ST can multitask (with RTX), has professional WP programs and data bases, runs software from other computers, and does many other things. But I wouldn't know it if I didn't do all the work to find these things - except for a few major packages. Most people can name more games than utility programs for the ST. If someone ported hypercard and improved it on the ST, Atari would probabaly say, "that's nice, but we are too busy with other things to bother".
They make the hardware, but we make it useful.

2045. Re: Laser C

Newsgroup: comp.sys.atari.st

From: michel@megamax.UUCP
Message-ID: <1282@megamax.UUCP>
Source record: 254245

There is NO limit to the size of ANYTHING in the new Laser C. However,
the problem you experienced is due to an inefficiency in the C compiler.
For each piece of data in an initialized structure or array a 32 byte
node is created. (This is REALLY DUMB!) This leads to a pig out on available
RAM. The compiler is then terminated by the shell because it ran out of memory.

I will fix the compiler and anyone who needs a copy just give me a call.

The GDOS font editor I mentioned in a previous posting is called FONZ. It supposedly can convert Mac and Amiga fonts to GDOS fonts, can scale GDOS fonts, and includes a font editor. At HT Electronics they had many disks full of GDOS fonts created with FONZ, including a bunch from the Mac. They said that HT Electronics was trying to find a distributor for the program, and did not know when it would be available.

I didn't make it clear in my previous posting, but Atari's Microsoft Write does not include GDOS support for the Epson FX-80 printer. At HT Electronics they were using an FX-80 device driver and fonts from Easy Draw for output from Microsoft Write on a Star printer. This and the lack of a spelling checker sort of cripple Microsoft Write in my view.

2048. Microsoft Write for the Atari ST

Newsgroup: comp.sys.atari.st
Date: 1988-02-26 01:25:45 UTC
From: Flash@UMass.BITNET
Message-ID: <880225202001D7F.AYOA@Mars.UCC.UMass.EDU>
Source record: 254248

Microsoft Write for the Atari ST comes with a set of GDOS Screen
fonts, and a set of ATARI DOT MATRIX GDOS fonts.

These dot matrix fonts, are of a DIFFERENT size and proportion than the
ones you would use on an EPSON COMPATIBLE printer.

Atari, in some show of inner light, have decided that no other printer
exists except their own wimpy dot matrix printer.

Oh yes, if you buy the laser printer, you get a set of fonts for that.

But what if you own an EPSON compatible printer like 90% of all ST owners?
Well, you have three choices:

1. Don't buy Microsoft Write.
(Wait for WordUp)
2. Buy FONTZ! and try to custom modify your fonts to the size needed for
and epson printer, learn assembly and write a FX80.SYS
3. Buy EASY-DRAW from Migraph, they come with a set of EPSON GDOS FONTS that
work with Microsoft write.

Since I own Easy-Draw I was able to go that way, but obviously Atari is not
really pushing Microsoft Write, since they only expect 5% of all the ST
population to use it. (Those who own Atari Dot Matrix Printers).

Oh yes, Microsoft Write WILL print in ASCII to just about any printer, but
who wants it to do that?

... more description...

Thanks for this nice review. I have only TWO questions before I hurry out the door and get this package:
1) Since the editor is now part of the shell, does that mean I wouldn't be able to use another editor? (I've been spoiled by Tempus, I guess :-)

2) Does Laser C handle arrays bigger than 32k?

I would really appreciate info on these two points, either by e-mail or by posting the answers.

2051. Re: rf modulaters

Newsgroup: comp.sys.atari.st
Date: 1988-02-26 04:35:00 UTC
From: Friesen@HIS-PHOENIX-MULTICS.ARPA
Message-ID: <880226043558.316445@HIS-PHOENIX-MULTICS.ARPA>
Source record: 254051

Hello,

I am behind in the forum here, had some difficulties with recieving it, so I am still reading entries from before Christmas.

I noticed that there has been lots of talk about RF modulators and am surprised that no one has responded with help. I have a (ok 1040 owners, drool:-)) 1040STF, actually a modified 1040ST.

I was surprised that noone has given any usefull info. on the subject. Well I guess I will have to fill the void.

FOLLOW THESE INSTRUCTIONS.

1. Take your ST to you local service center (mine is only 40 miles away:-))

2. Ask the person to install an RF modulator

3. Later, pick up your ST and pay the person $60.

That's how I got my RF modulator installed in my 1040 ST, and have hooked it to my VCR many times to record presentations, demos, ect. It works fairly well. It is of coarse a little blurry, because of the low resolution on a TV, however, it is very sufficiant. When I first hooked it up, I had snow on the screen, I called the service place, and they said that it might be the cable I hooked it up with. I then used a cable I had pulled off of an old 2600, and it works great.

This isn't a new product, I had this done back in September.

The resolution, as I said was is somewhat blurry, and if you display text, you probably want it to be a sufficiant size, but I have been very satisfied.

A word to the wise... If your VCR or TV does not have manual fine tuning, you may have problems. My television set has permanent autamatic tuning, and had some interference, however, my VCR has both automatic and manual tuning, so I hook my computer to it and manually fine tune it. I am not saying that you cannot hook your computer to a TV with permanent fine tuning, just relaying my experience.

For you hardware hackers out there (I shudder at the thought of taking apart my ST) I don't think the RF modulator operation is to involved. Although the service man wouldn't give any specifics, he implied the most difficult part was drilling the hole in the back of the computer.

Yeah, right.

Um, at the potential expense of becoming a pest, I wish to state that
I sincerely hope that Megamax did not label a set of disks and send
them out containing nothing useful. Such an action would be quite
unworthy of any professional software company.

I also wish to mention that I intend to upgrade my Megamax as soon as
some reliable upgrade to Laser is available. I will most likely not use
it much, since I have MWC, but will certainly attempt compiles of the
stuff I port upon it.

I know what you mean about not grabbing at it! Paul Heckel of "Zoomracks" fame - the package called "something like Hypercard" by John Sculley, has been trying to get a contract signed by Atari for months now. Atari contacted him, provided him with their set contract and Paul worked with an attorney to review and revise portions. Re-submitted it to Atari, and no word for months! As it stands, he is still waiting for word. Who knows, maybe its of no interest since the new Abaq is in development.

2057. Re: Closing desk accessories

Newsgroup: comp.sys.atari.st
Date: 1988-02-26 16:17:42 UTC
From: Gribnif@UMass.BITNET
Message-ID: <880226111414E67.BCMH@Mars.UCC.UMass.EDU>
Source record: 254057

Greetings!

In my previous letter I was looking for a way to close desk accessories before using Pexec() to call a second GEM application from within a program. Well, I have found something that seems to work (after finally discovering some docs that actually explain the way appl_write() REALLY works). The following code segment seems to do the trick.

```
int buff[8], w_hand, i, AES_handle, dum;

AES_handle = appl_init(); /* get the handle of my application */
.
. /* the guts */
. /* close any windows still open */
wind_get( 0, WF_TOP, &w_hand, &dum, &dum, &dum ); /* topmost window */
while( w_hand > 0 ) { /* until no more windows */
wind_close( w_hand );
wind_delete( w_hand ); /* now the next one down is top */
wind_get( 0, WF_TOP, &w_hand, &dum, &dum, &dum ); /* get the next one */
}

buff[0] = AC_CLOSE; /* emulate the message normally received */
buff[1] = AES_handle; /* handle of app. that caused the close */
for( i=0; i<AES_handle; i++ ) { /* assume the DAs have lower handles */
buff[2] = 2+i; /* an educated guess */
appl_write( i, 16, buff ); /* the message is read the next time the */
} /* DA does evnt_mesag() or evnt_multi() */
```

I am just wondering two things: first, is it safe to assume that any DAs will have AES handles less than the current application? Second, assuming a DA actually does care what menu id (as stored in buff[2]) the DA is assigned to would my little guess be correct? Granted, there really is no reason I can see why a DA should care if the menu id passed matches what it sees as being correct, but considering how few correctly written DAs there are out there, who knows.

Now for my opinion on the Copyright issue....naw, just kidding.

Dan Wilga

2058. Posting Binaries - please read

Newsgroup: comp.sys.atari.st
Date: 1988-02-26 16:42:17 UTC
From: lean@sbcs.sunysb.edu
Message-ID: <994@sbcs.sunysb.edu>
Source record: 254058

Since James (x-moderator) has relinquished his role, here goes:

To all those who intend on posting binaries to comp.sys.atari.st,
PLEASE include a decent amount of ENGLISH prose (ie. before the uuencoded
stuff starts), describing what the program you're posting is supposed
to do. PLEASE be as complete and concise as possible (as was done by
James previously), that is specify:
1) whether for mono, color, or both
2) binaries, sources (specify MWC, OSS Pascal, etc), or both
3) what it does (be as complete as possible here)
4) what special hardware/software configuration may be needed

It's silly to post a 50K uuencoded thing which is preceded by 2 lines saying
it's a blah, blah, blah. A reasonably complete description of what the
program does (in ENGLISH , and not uuencoded) should be included, so the
reader can determine if it's something he/she wants without having to download
, decode, and de-arc it first. Of course the FULL docs should be in the
encoded file. REMEMBER, most people who are reading your posting have no idea
what your program does; hence 2 lines of doc might be enough for you (like
saying it's a f_sel program), but would be insufficient for most of us.
Thanks in advance.

2060. Re: Atari no-support?

Newsgroup: comp.sys.atari.st
Date: 1988-02-26 17:25:38 UTC
From: good@atari.UUCP
Message-ID: <996@atari.UUCP>
Source record: 254060

In a recent article, the question was raised as to whether Atari will drop the ST/Mega line in favor of the '030 or Abaq. The answer is simple: NO WAY!!!

Engineering currently has in development or planned several variations on the ST, with features to address different needs, as well as general enhancements. And great care is being taken to maintain maximum compatibility with the current ST/Mega series. These products are all in addition to the "basic ST" you all seem to know and for the most part love.

The '030 and Abaq-type products address a different market segment than the ST and Mega, and will peacefully coexist with probably very little overlap. And yes, we are planning paths to interconnect the whole range for whatever purposes you might dream up!

So rest assured, not only is the ST architecture going to be around for a long time, it will be complemented by future product offerings. One of the big strengths of the ST is the software available for it, and it would be very silly to walk away from such a base. We may be a lot of things in the eyes of the users, but we're not that insensitive. Jack Tramiel's open philosophy is, paraphrased, "power for the masses", and the '030 and Abaq will not be at 'mass pricing' until several critical component costs are literally decimated.

So keep those ST applications rolling!

Roy J. Good
Product Development, Atari Corporation

Views expressed are my own. Atari may agree or disagree; they have the right.

I have to disagree a little about the lack of an MMU and a _real_ operating system. If you want a real operating system on the ST look into getting IDRIS. It is a very nice Unix environment that does not require an MMU. It has a good C compiler available, a Pascal compiler (actually a Pascal to C translator), and a source level debugger (cdb), along with a lot of the standard Unix utilitys. I wish more people would look into it. It is by far a giant leap above TOS.

2064. fonts newsgroup

Newsgroup: comp.sys.atari.st
Date: 1988-02-26 19:37:26 UTC
From: richard@gryphon.CTS.COM
Message-ID: <2711@gryphon.CTS.COM>
Source record: 254064
Cross-posted to: news.groups,alt.config,comp.sys.amiga,comp.sys.apollo,comp.sys.atari.st,comp.sys.ibm.pc,comp.sys.mac,comp.text,comp.lang.postscript

I propose a newsgroup on the topic of fonts.

Aesthetics, legal issues, "whats available", "where can I get it"

...that sort of stuff.

This is an official (well, as official as it gets) call for votes.

I will count votes EMAILED to me at one of the addresses below
starting today, February 26, 1987, and will collect votes for 30
days. If we get 100 more yes than no votes, it will be comp.fonts,
otherwise after the obligatory discussion, it will be alt.fonts.

If you see this message more than once, chalk it up to...uhh, experience.

Followups to the appropriate group; edit the newsgroups line.

>C'mon, if you've got something to say, let's get it out into the open...

Do you really want to know? (y'all that is, not just Robert)
Are you ready for the reality of it? You may not like the answer.

Developers do have gripes with Atari. Some major gripes and some not so
major gripes. But Atari has to push really hard to get us to speak up.
Becuase everytime we flame Atari, we are potentialy hurting ourselves.
First, we get on Atari's bad side. And when you're on their "black list"
things get tough, believe me, I've been there (I may be heading there again).
It takes some guts (and maybe stupidity) to speak up against Atari. Also
when the Atari market is already not so good, it doesn't help to have the
major developers flaming; the developers' own business is affected. That's
why most developers just ride along, and keep to themselves about their
gripes. That's also why the ST magazines (so-called journalists) never
flame Atari. For one thing, some (like Antic) sell the damned products!
They're sure as hell not going to flame their own wares!

In the end, you are absolutly correct Robert, the regular "Joe-user"
is the one that pays. We all took a risk; we hoped Atari would make
it worthwhile. I've got 3-years and all my money in this thing; if
the ST dies, all I've got to show for it is a lot of experience and a
few new friends.

And who at Atari is listening? That's a good question. But even better:
what would they do about it anyway?

To really discuss this, we need a new newsgroup: comp.sys.atari.flame

I'm too much of a whimp to say much more (this week). But if things
continue the way they've been going... I've got plenty to say (If anybody
still wants to hear it).

Subject: Atari ABAQ and MJC PDCC compiler

One of the local shops is traveling around Scotland showing off
the developer's ABAQ, which is supposedly available "real soon
now" here in Britain. (I'll have a chance to see it next week --
will post something if worthwhile.)

On a different note, I have a Mega ST2. When I tried the PD CC
compiler, it worked fine until I had to reboot the system a few
days later. It then would go into an infinite loop when doing
the assembly stage! After much experimentation, I found that
everything works fine so long as my free mem (largest chunk
thereof, as returned by Malloc( -1L ) ) was less than about half
a meg. If it went any higher than that, presto: infinite loop!
So now I have to (:-) boot up with 1.5meg worth of ramdisks to be
able to use this compiler, which, by the way, I like very much.
It's great for quick and dirty programs!

Has anybody run into this before? I don't know what happens on
1040's or upgraded 520's... I have only tried this on the Mega
ST2.

Cheers!

Message-ID: <8802280455.AA06317@ucbvax.Berkeley.EDU>
Source record: 254067

Here's two differences I've run across between GEMDOS formatted disks and MSDOS formatted disks:

1) size of FAT, the following information compares the disk usage of a GEMDOS disk and MSDOS 3.3 disk, both formatted to 720K. The numbers in the format a/b indicate the count of sectors for GEMDOS/MSDOS.
Start Length
FAT 1 1/1 5/3
FAT 2 6/4 5/3
Root Dir. 11/7 7/7
Free Space 18/14 1422/1426
Note that the FAT on MSDOS is only 3 sectors long, since only about 1100 bytes are needed for the FAT. (Anyone know why GEMDOS needs more??). MSDOS is thus able to cram an extra 4K of free space on each disk.

This leads to a big problem, which I believe someone was complaing about a while ago. If you click on the A icon, and open a window for the A:\ directory (GEMDOS disk), then remove it and insert an MSDOS disk, press Esc to get a new directory, you sometimes get 0 bytes in 0 items. If you close the window and then click on A again, you'll get the correct directory. It seems that GEMDOS does not check the location of the directory when you insert a new disk. But it does when you first open the window. (Why?????).

2) Volume label files have different attribute bytes. A normal file has an attribute byte of $00. This means that it is not read-only, not a directory, not a volume entry. When you format a disk on GEMDOS and give it a name (a volume name), it creates a directory entry with an attribyte byte of $08. MSDOS uses a value of $28.

This again causes some problems. If you do a directory of an MSDOS disk, the volume name appears as a zero length file (which can be deleted). Why does GEMDOS do this? Is it that hard to use the proper attribute byte an the same sized FAT???

I think your note would have been better if you would have tried to
inform the rest of us in netland as to exactly why you are so peeved.

As to flaming Atari Corp., the only purpose that serves is to drive down
morale. If you have a beef that really deserves attention, write a
letter to Atari customer relations and/or management and/or the main
stockholders. Nothing like applying pressure at the top. (Actually, I
am not sure of Atari's corporate structure. How difficult would it be
to send a letter to Leonard Tramiel, for example, and any chance he would
read it? Same question for main stockholders.)

>Works for him. He had 8 people in shipping, last I heard.

PC-WRITE and PC-FILE are major exceptions to the rule (as a matter of fact, a company I consult for bought a copy of PC-FILE). The fact is, most shareware authors get no contributions at all. I would like to see every fine program rewarded with lots of money and praise, but it just doesn't happen in the real world.

I think the PC-FILE and PC-WRITE programs succeed so well exactly because of the reasons stated. The programs have just enough docs to show how useful they are without giving you full control. A registered copy gives you very good printed docs and very good support.

>> [me]

homebrew isatty delete]

The MWC library does have the "isatty()" function... I just checked.
I believe it has had that function since version 1.0, but I can't be
sure. It may not be documented, but it is there. You may find doing
an "nm -g libc.a" some time -- You'd be suprised to see how many functions
are there.

If you want a full list of the functions available in the MWC library posted,
I'd be happy to do so, but as I work for MWC, some may find the posting to
be a commercial use of the net, and I might get zapped for it.

> You, like the other person who was
> disappointed by the lack of "sales" of their terminal emulator (no matter how
> nifty), were targetting a oversaturated market. How about writing a program
> that no-one has even thought about writing?

As the "other person who was disappointed by the lack of ``sales''", I'm
getting tired of the backhanded slams I'm getting from people.

1. This was two years ago.

2. This is still the only terminal program I've seen for the IBM-PC
that emulates the VT100 well enough to keep EDT happy on both RSX
and VAX/VMS.

3. This is still the only terminal program that understands that an
IBM-PC has two serial ports... and allows you to use them both
effectively.

4. And it's MUCH smaller than any of the "big name" programs out
there. It runs quite happily in a 192K DoubleDOS partition. Given
that COMMAND.COM and a bunch of buffers have to fit in there as
well that's pretty good. It may (it's been a while) even run in
128K.

5. (to the people telling me nobody ever saw it) It was posted on
UseNet. So you should have seen it.

I was primarily "selling" it to see if I could get some feedback on what I
could do to improve it. And, I must admit, to get some ego boost. I had
previously sent stuff out freeware and gotten nary a nibble. I guess this
disqualifies me as a shareware author, but I've not noted that anyone else
has done that much better.

Since then I've given up on shareware. A piece of freeware that I recently
posted to comp.sources.amiga and Compu$erve has now produced commercial
interest. Let's see if Software Terrorism works any better.

2079. The ConTEXT Editor

Newsgroup: comp.sys.atari.st
Date: 1988-02-27 19:26:14 UTC
From: pchris@sim.Berkeley.EDU
Message-ID: <1065@pasteur.Berkeley.Edu>
Source record: 254081

Hi Netlanders,
I recently came across a great shareware editor. It's called ConTEXT written by Don Milne (I got it on the Atari BBS under CONTXTV2.ARC). It was made to replace the TDI Modula2 editor, and if they still have the same editor they had two years ago, getting the ConTEXT editor is a MUST if you work with TDI Modula2. It supports the error insertion of the TDI editor.

There are several great things about this editor. It is a GEM based editor, and about the fastest that I have seen. But the really nice thing is that it is Word Star compatible, so you aren't bound to the mouse (though you can use it) like other GEM editors (notably Megamax C's). The cursor keys also work correctly (unlike Megamax C's editor). Inserting text is very fast, and scrolling is faster than other GEM editors. The commands can have their key bindings changed, and there are macros. Overall, this editor appears to be a professional product.

There are a few problems (annoyances) with this editor:
i) It does not support hard tabs: instead, when you tab, the editor inserts spaces, so to delete a tab means deleting 8 spaces. I don't know why so many editor authors like this feature, but it is an annoyance since it is slower (decreases productivity) and takes more memory. At least make this feature reconfigurable, instead of hardwiring it into the code.
ii) The file selector has a default mask of '*.MOD' for modula2 source. This can not be reconfigured (unlike other default settings), and is an annoyance when not working with Modula2.
iii) Only one file can be edited at a time. The multiple windows/open files of the Megamax C editor is a definite advantage, especially with cut and paste between the windows/files. This is definitely needed in the ConTEXT editor.
iv) The editor appears to only be able to edit up to 64K files. If you do block copy insertions to get to this limit, it will warn you that there is not enough memory. But I tested it once by inserting characters at this limit, and a Modula2 runtime error popped up, which forced me to exit the program, thus losing the file. Normally, this limit is not a problem.

The docs say this program was originally uploaded to BIX. I'm a poor and destitute student, so I can't afford BIX. If someone can contact the author (BIX-ID: "mpack" (MicroPack Ltd.)) and relay the above comments, I would be grateful. I am willing to pay $40 - $50 for ConTEXT with the above problems/annoyances solved. Also, if a new version (I have version 2) of ConTEXT exists on BIX, could someone download it to the Atari BBS?

As a programmer, I spend a lot of time in editors. It is difficult to find an editor that works like I do, but after trying a lot of editors on the ST (I have tried the three VI emulators: LEVEE is the best, though it still

has several annoying problems I can't live with. I don't do EMACS), I have found ConTEXT to be very good, and would be even better with the problems above solved.

Thanks for listening,

Chris Perleberg

[more deleted stuff]

Dave, just get yourself under the Federal Witness Protection Program and then you can spill your guts without having to worry about 'retaliation' from Atari Corp. :-)

I think a "gripe-group" for the ST is a good idea, but only if we can be sure that Atari reads those gripes AND takes them to heart. I have a few gripes myself and would certainly be able to contribute (to a small extent) to this new group. But then, we might as well forget this idea: I don't think Atari (the higher management that is) cares too much about us Joe User's as long as they can make a good profit WITHOUT the "hassle" of responding to customer complaints!
I'm not sayig that there isn't ANYONE at Atari that listens (Neil and Allen are good examples and are excluded from this "flame"), but I'm not at all sure as to how many of our concerns make it to the 'decision makers' in the company.

Enough said. I certainly don't want ST sales to suffer just because I spoke my mind. After all, the machine is a very nice (and successful - at least in Europe :-) one.

>Works for him. He had 8 people in shipping, last I heard.

I'm tired of hearing this. That company is the most prosperous of a group
that you can count on your fingers. The other 20,000 "shareware" programs
have all been dismal financial failures that haven't returned anything,
and certainly not something similar to what the author would have made
as a programmer or consultant in regular employment.

As he points out, it's not even the shareware concept that's the success.
It's selling the manuals and support. I daresay there are many companies
selling training, books and support for Lotus 1-2-3 or MS-DOS that have
made more money than anybody's made from shareware.

>> Lack of a MMU us going to kill the ST for any _real_ Operating Systems!
>
>I have to disagree a little about the lack of an MMU and a _real_ operating
>system.

There are a lot of things you don't need on a computer. You don't need a large linear address space, undifferentiated registers, a 32 bit ALU, or a stack.

However, each of these is valuable out of proportion to its cost. With them we can easily run large programs with large data structures, we can have compilers generate nice expression computation code, and we can stack allocate frames for subroutine instantiation.

So it is with an MMU: it allows flexibility in memory allocation; it protects the operating system and individual process memory spaces. If Atari's had MMUs they would be great, instead of pathetic. [Insert standard TOS disgust.]

These features are essential for building reliable and powerful operating systems. I would not have much faith in a UNIX lookalike that didn't have hardware memory protection, and I wouldn't use one in an application where reliability and resistance to attack were a concern.

It is my belief, that in these days of advanced CS (cough), no software or hardware designer should take seriously (in a technical sense, ignoring crass economic issues) a computer that doesn't have an MMU. It's like the old saw about the dancing bear: it's not how well operating systems work with no MMUs, it's that they do it at all.

Tracy "message passing forever" Tims
(ttims@watdcsu.waterloo.edu, mollusc@csri.toronto.edu, TTIMS@WATDCS.BITNET)

PS. I thought the debate about multiprocessing was pretty funny, too. It was like listening to a bunch of virgins tell me I don't really need sex.

PPS. I'd love to have Coherent on my ST.

2086. Re: Changing to / in TOS

Might I be permitted a bit of sinful glee, now?

After all, when I bought my Amiga (and for the previous months during which I was contemplating the purchase of an Amiga) I had to put up with endless harping by Atari ST owners on all the bug-fixes Commodore was putting out.

I shouldn't say "I told you so", since it's unlikely any of the people in this newsgroup were involved...

2087. FREE USENET/MAIL FEEDS AVAILABLE (WITH TELEBIT & HST SUPPORT)

Newsgroup: comp.sys.atari.st
Date: 1988-02-28 01:11:17 UTC
From: raj@spl1.UUCP
Message-ID: <973@spl1.UUCP>
Source record: 254088

```
**************************************************************************
**************************************************************************
I've been getting some regular mail asking if we're still offering free
feeds and mail gateways, the answer is a most emphatic YES, so I'm
reposting this notice.
**************************************************************************
**************************************************************************

We would like to let all you netlanders know that site spl1 is available to
provide high speed news feeds and mail links to all eligable organizations
*WITH* *NO* *ADMINISTRATION* *OR* *SERVICE* *CHAREGES*

spl1 is located in downtown Chicago and now has multiple USR Courrier HST's,
TELEBIT TRAILBLAZERS, and a gaggle of vanilla 2400BPS modems online
on our news/mail engine machine to support feeds.

The site is accessable through PC Persuit and operates 24 Hours/Day 7
Days/Week, dedicated to news and mail.

If there any sites which are interested in:

o Getting a news feed
o Switching their feed to a high speed (Telebit or HST)
DDD/ (your) Out WATS site
o Picking up alt, biz, unix-pc or other non-standard groups,

we would be happy to accept new users (again, no fees involved).

Sound too good to be true? It's not. spl1 is now feeding sites like
Arthur Anderson's Corporate Offices, AT&T's National Tech Support Center,
The Santa Cruz Operation, The Internal Revenue Service, Beatrice Foods'
Corporate Offices, Reuter's Rich Inc, and others.

spl1 is well connected to both east and west coast sites and maintains
exceptional email delivery performance.

We've been up continuously for 60 days (knock on wood, a good indicator of
reliability) and haven't yet missed a feed for our sites.

Qualification for connection to our site is a function of the number of
news readers your site supports and your willingness to offer downstream
feeds. We want to help extend and support USENET, helping a good thing
get better.

Well, here I am again bringing up my favourite topic
once more. Sorry to bother you again as most of you seem totally uninterested.
There was no reply to my last letter and I am about to give up.
One last (well, no warranty...) try follows.
Is anybody on the net willing to run two or three benchmarks on an ST
under Idris and under OS-9? I can send you the sources or alternatively
tell you where to find them. Some of the sources we have are in C and some
in FORTRAN. The tests I am thinking of are for instance: dhrystone, whetstone,
and linpack.
In an earlier letter I mentioned the OS's EUMEL and RTOS-UH. I said if noone
else does it I would be ready to write a short description. I don't know too
much about them, though. How many people would be (seriously) interested in
such a thing?
Come on, friends, don't let me despair
Yours

In article <153@bdt.UUCP> david@bdt.UUCP (David Beckemeyer) writes:
>Becuase everytime we flame Atari, we are potentialy hurting ourselves.
>First, we get on Atari's bad side. And when you're on their "black list"
>things get tough, believe me, I've been there (I may be heading there again).

Are you saying CENSORSHIP? That's terrible!

>It takes some guts (and maybe stupidity) to speak up against Atari. Also
>when the Atari market is already not so good, it doesn't help to have the
>major developers flaming; the developers' own business is affected. That's
>why most developers just ride along, and keep to themselves about their
>gripes. That's also why the ST magazines (so-called journalists) never
>flame Atari. For one thing, some (like Antic) sell the damned products!
>They're sure as hell not going to flame their own wares!

That's certainly true. However, there must be a line drawn between just
plain malicious flaming, and sincere wishes for improvements. The truth
hurts, and I wonder why Atari can't(?) take constructive criticism.

>And who at Atari is listening? That's a good question. But even better:
>what would they do about it anyway?
>
>To really discuss this, we need a new newsgroup: comp.sys.atari.flame

No, what we ALL need is what should have been there all along: A
DIRECT pipeline to Atari's top management.

What I'd imagine could be very simple: How about a secretary and a
mailing address? The secretary's SOLE task is to read the mail, and scan the
nets/services, for Atari-oriented criticisms and comments. Then, this
ssecretary would make a report to top management (Jack?), who'd (hopefully)
take heed and do SOMEthing about the whole thing.

We know Jack Tramiel can make things move when he really wants to; Putting
together a prototype 68000 machine in six months is an amazing task. Why
aren't we seeing such dynamic energies and deep concern for states now?

My God, even a comic-book company listens to its readers. Apple must have
one truckload of a consumer-relations department. What does Atari have? I'm
not saying that a lot of money must be invested or anything; Just give us
SOMEwhere to air our views, with assurances that they will be heard.

I dunno, maybe I'm just naieve about how big business works. But I've
always believed that, if you're running a PUBLIC service, you better listen
to your public -- Without them, you're nothing. I help run a local Atari
BBS, for instance, and we practically ENCOURAGE our users to fire away and
flame at what they don't like. Maybe not all of the arguments are valid, but

we DO listen. Why not Atari?

Okay, enough negative flaming (boy I feel depressed again)...I want to restate that I am one of the BIGGEST Atari fans around (grin). My idea of fun is making Apple users turn green when my ST runs rings around their hardware. All of us out here want to see Atari thrive, but to do so, SOMEBODY must listen to us, and fix what's wrong. And if it must hurt, to say that TOS has bugs, or that we don't like the "announce now, release next decade" policy, or the keyboard of the ST isn't perfect -- Then that's what the public wants, and something better be done.

Is anyone listening?

--R.J.
B-)

P.S. When Jack Tramiel first bought atari from Warner, and turned everything around almost overnight, we were all so happy, and had a sense that things were being done. Is it me, or has the momentum slowed?

2090. Calling GEM from TOS

Newsgroup: comp.sys.atari.st
Date: 1988-02-28 05:23:10 UTC
From: pchris@sim.Berkeley.EDU
Message-ID: <1079@pasteur.Berkeley.Edu>
Source record: 254092

******
Does anybody know if you can execute a GEM program from a TOS program? The reason I ask is I would like to execute GEM 68000 programs from Atari's CP/M emulator (a TOS program). This could be done by executing an IN/OUT z80 instruction inside the emulator which would then call a 68000 driver which could call the GEM program. Editing is slow with a CP/M editor, so being able to run a GEM program would increase programming productivity.

Thanks,
Chris Perleberg
pchris@sim.berkeley.edu

2091. DISKSCAN 1.00 - Disk Manager (1 of 2)

Newsgroup: comp.sys.atari.st
Date: 1988-02-28 06:00:37 UTC
From: trb@stag.UUCP
Message-ID: <348@stag.UUCP>
Source record: 254093

Hi,

Since I have shelved DISKTOP for a bit, I thought I would combine DISKTOP and HDSCAN and produce a new program. DISKSCAN 1.0 is included in this release. DISKSCAN is a FREE (but copyrighted by me) program that has pretty much all the features of both DISKTOP and HDSCAN. It is a fully functional program with lots of features and, in keeping with the HDSCAN tradition, I have reserved only a few additional bells and whistles for the Professional version (2.0 = not free). In this case, these extra features include things like sort options, mouse control, extra output options, etc, all of which you can live without if you are strapped for money. To keep things simple, the following document covers the features of both 1.0 and 2.0.

Some useful things to note. This version of DISKSCAN (1.0) has extended command macro features, better directory viewing, and a few other enhancements that were added to HDSCAN 1.4/2.4 (just finishing the docs on that). So if you are familiar with the old HDSCAN I would still recommend reading the docs.

-Todd Burkey
trb@stag.UUCP

P.S. Please excuse any typos or cross-references to HDSCAN in this document. I haven't had any free time to clean it up and thought it would be best to at least get something out now before I get tied up with testing HDSCAN 1.4...

This release is arranged in two parts:
Part 1: diskscan.doc (this file)
Part 2: dscan100.uue (an arc of dscan100.prg and diskscan.key)
-------C--U--T-----H-E-R-E---------------------------------------

DISKSCAN Version 1.0/2.0
(The ST Floppy Disk Manager)
(c) 1988
by Todd Burkey

Note: This documentation must be included with DISKSCAN Version 1.0 if you wish to transmit the program to anyone by email, bbs, or any other means.

Any modification of the binaries or this document is expressly forbidden. DISKSCAN 1.0 is copyrighted 1988 by Todd Burkey-All Rights Reserved.

DISCLAIMER: I spend all my money on computers that outdate themselves within a year, so I really don't need a disclaimer...although with all the strange things TOS and GEM occasionally do, I should say "LET THE USER BEWARE". There. Safe.

1.0 INTRO:

DISKSCAN was designed initially to satisfy a simple need. I kept losing files. Not permanently, but just in that frustrating sense of knowing that one of those disks with the little cryptic writing on the plastic contains the file I want. And also knowing it is going to be on the very last diskette that I stick in the drive. So, DISKSCAN is first and foremost a utility that lets you 1) archive file information quickly and painlessly and 2) easily find the files at a later date.

A program I wrote almost two years ago (DISKTOP) had covered this problem fairly well, but I quickly ran into limitations in how many disks I could adequately archive with it (both array limitations and the user interface). DISKSCAN is hopefully my final solution to the problem. DISKSCAN bypasses the old 2000 file limit (currently it is set to 5000 files/database), but also keeps track of what directory a file is in, its' size, and its' date. And, since you can have multiple databases there really aren't any hardnosed limitations anymore.

You will find that DISKSCAN is optimized for speed. It scans disks quickly and, by letting you use the volume name, lets you scan your existing disk collection with a bare minumum of effort. DISKSCAN also recognizes the DISKTOP.INF file which was used by DISKTOP (it is a small file that just contains the name of the disk...up to 20 chars long). By default, DISKSCAN will still look for the DISKTOP.INF file and create one for you if you put in a disk that doesn't have the file. This feature can be easily disabled by one keypress (or by setting a configuration parameter...see the discussion on DISKSCAN.KEY). I call it a feature because I prefer to call my disks by a name like: "Source Code Disk #1" as opposed to a yucky SRC_CODE.001 volume name.

Other features include viewing files, hexdumping files, tagging for copying and or deleting groups of files, renaming files, changing protections on files, invoking external programs, and sorting files. You can sort by date, name, and size in ascending or descending order. For example, you can select all .c files (all disks), sort them by reverse date, then easily track down that elusive program you lost. Or maybe sort an entire library by name to help find duplicate files (this will make more sense if you have as many disks as I do). The sort in DISKSCAN is a recursive quicksort, so even thousands of files will be sorted in a few seconds. I have also added a very simple (but fast) file compare routine to allow quick checks to see if files are duplicates. And you will find even more features embedded in the program as you start using it.

1.1 BRIEF HISTORY:

I wrote this program for one reason only...I needed it.

1.1.1 Who else needs it?

Anyone who has more than 20 floppies laying around can probably use a quick archiving mechanism. DISKSCAN's predecessor (DISKTOP) was used heavily by the local Atari clubs to keep track of files and to provide a simple way of letting members find the right disks to buy. As a developer, I have little trust in hard disks, so I tend to back certain files up to lots of temporary

disks and DISKSCAN has proven invaluable for keeping track of my mess.

2.0.0 USING DISKSCAN:

2.1.0 First things first: The DISKSCAN.KEY Control File

Before you run DISKSCAN for the first time, you should probably create a file called DISKSCAN.KEY and place it in C:\DISKSCAN.KEY or on your floppy if you don't have a harddisk and don't trust your ram disk. DISKSCAN will search for DISKSCAN.KEY in your current directory when you first invoke DISKSCAN, and if it can't find it there, it will automatically check C:\DISKSCAN.KEY. If DISKSCAN doesn't find it, DISKSCAN will come up with some defaults of its own.

DISKSCAN.KEY is control file that defines system and user specific things for DISKSCAN. This includes 'things' like telling DISKSCAN where your best editor is located, where to find your copy of arc, or even what commands to 'attach' to the auto-invoke keys (Function Keys 1-10) for macros. While DISKSCAN will work fine without DISKSCAN.KEY, proper setup of the file will be well worth the time it takes to learn its somewhat cryptic structure.

2.1.1 DISKSCAN.KEY Syntax

The format of DISKSCAN.KEY is actually very simple. Each line in the file acts as either a key definition (keys F1-F10), a parameter assignment, or a comment. If a line does not have an equal sign ('=') or colon (':') in the second character position, it is taken as a comment line.

2.1.1.1 DISKSCAN.KEY Key Bindings

If the line begins with one number followed by an '=' sign, then the text that follows the equal sign will be taken as a command (or commands) to be executed when you press the appropriate number key. These commands can consist of pretty much anything you would normally type from a shell. A nice feature is that the commands can be parameterized by embedding @F, @P, @f, @p, ?, and < in the command line. This will make more sense once you start using DISKSCAN, but @F will expand into the full pathname of the file you are 'ON' when you select the command, @P will be the full file name without the extender (i.e. if C:\trb\test.c is the FULL pathname, then @P will expand to C:\trb\test). Likewise, @f will give you the full file name (test.c) and @p will give just the prefix of the name (test). Finally, if the first character of the command line is a ? the user will be prompted before the command is invoked, and if it is a < then the user will be prompted to type in the full command.

2.1.1.2 DISKSCAN.KEY Parameters

If the line begins with a letter, dash ('-'), or plus ('+') followed by a ':', then the information following the ':' will be passed (kind of like parameters) into DISKSCAN at startup. I know, I could have used environment variables, but this was easier and simpler for people to set up. For now, the 'parameters' that are recognized by DISKSCAN are:

'A' (arc path)
'P' (print file path)

'E' (editor path)
'+' Use the following floppy drive for scanning (default is drive A)
'V' If set to Y then the Volume name is scanned instead of DISKTOP.INF

2.1.2 HDSCAN.KEY Example

For example, let's say your favorite editor is in C:\bin\emacs.tos, you
have arc in your local directory, you always want drive B scanned,
and you want to be able to perform a variety of commands on files at the
press of the key. The following DISKSCAN.KEY file would accomplish this.

```
-------sample DISKSCAN.KEY file--------
+:B
E:C:\bin\emacs.tos
A:arc.ttp
V:Y
/* Key 1 & F1 definition: do a word count of the current file */
1=wc @F
/* compile the current file after prompting the user to do so */
2=?cc -O @F -o @P
/* do a less of the current file */
3=less @F
/* drop into a shell...somewhat unnecessary on BSD systems */
5=C:\bin\sh.prg
/* copy the current file into my catchall directory */
6=C:\bin\cp.prg @F G:\packrat
/* Look at a tiny picture */
7=C:\tinylook.ttp @F
/* key 0 & F10 definition: dynamically prompt user for the command to issue */
0=<
-----end of sample DISKSCAN.KEY file--------
```

2.2.0 INVOKING THE PROGRAM:

Very simple. Just click on the hdscan.prg icon. Or you can run it from a
shell with command line options by typing:

hdscan data_base_name <--assuming you want to load a database other
than the standard "DISKSCAN.DB"

Note that with this format, you can also install the application with
a .DB extender and then just execute hdscan from the desktop by clicking
on the database file itself (assuming you use a .db extender).

The screen will be somewhat confusing to the beginner, so I will explain
here what you are looking at.

2.2.2 The Main Display:

Right after invoking DISKSCAN for the first time, you will probably see a
somewhat empty screen (because you haven't scanned anything yet). Probably
the best thing to do is to stick a disk in drive A and press the '!' key
to start a scan. If this disk has never been scanned before and you didn't

over-ride DISKSCAN's default use of DISKTOP.INF (note that this is NOT a typo for DESKTOP.INF!), then you will be prompted for the disks name. I recommend giving it the same name that you have scribbled on the top edge (or front) of the disk. Keep in mind that it must be 20 characters or less (DISKSCAN will just chop it off if you type too much). After you type it in, DISKSCAN will write out the file to the disk and scan the disk. Now you should have something on the screen to relate to in the following discussion.

Most noticeable on the screen will be a tall box near the right of the screen filled with file names. That is the 'selected file' window and you can scroll up and down through all selected files with the h, j, k, and l keys (more on this later) to quickly get to a file. The file you are currently 'ON' will be highlighted (both reverse fielded and with a > sign next to it). Right after scanning a disk, DISKSCAN sets the selection criteria to NEW DISK and selects, for viewing, only those files it just scanned.

As you scroll through the file names, notice that the directory the file is in, it's size, and it's dates (modify/access/change), are automatically updated in windows near the top left of the screen. The disk name is also updated (more important when you are searching for files...)

Next to the file size window is a window that will make more sense later. It displays the total size of all Tagged files. This proves useful when you are tagging files to copy to a RAM Disk, deciding which files will fit.

Below these two windows is a long window used for prompts. Look in this window if you aren't sure why something isn't happening...it might be asking you a question.

Below the prompt window is a big free space which I am sure will eventually get filled up. Right now it is mostly a billboard.

Below that is a status line that basically tells you 1) what you have selected (i.e. ALL will appear if all partitions are chosen, DISK will appear if you have selected a single directory to work in, and a string of 1-8 characters will appear if the selection was made using a wildcard string search), 2) the sort order (initially RANDOM to give you an idea of how fractured your file space is), 3) the number of disks total in your current database, 4) the number of selected files, and 5) the total size in bytes of all selected files.

3.0 File Selection Mode: Commands

You can skip this section and just use it for reference if you are familiar with the Unix version of HDSCAN. Everyone else would be wise to at least do a quick scan of the commands. One important difference to keep in mind between DISKSCAN and HDSCAN is that in HDSCAN, the files were always available throughout the session (i.e. you couldn't swap hard disks on me). In DISKSCAN, I actually check to see if the correct disk is in the drive before performing an operation (file viewing, deleting, copying, comparing, etc). If DISKSCAN doesn't see the correct disk in the drive, it will prompt you to put it in (or you can hit ESC to abort the operation.)

3.1 Moving About:

One important thing to learn before we get into the various commands is that to scroll through the files in the file window, you can use the h, j, k, and l keys. The j/k keys will scroll down/up in the file window respectively. Likewise, the h/l keys will page up/down in the list. If you want to go all the way up or down in the list of files displayed in the window, then use the H and L keys. If you have really slow terminals and still want to use HDSCAN for some reason, use the J/K keys instead of the j/k keys. This will cause scrolling without updating the current file info on the screen.

For those of you who prefer the use of the arrow keys, then make the following substitutions to the above:

Up Arrow---->k key-->scroll up
Down Arrow-->j key-->scroll down
Left Arrow-->h key-->page up
Right Arrow->l key-->page down
Shift Up Arrow---->K key-->scroll up (faster)
Shift Down Arrow-->J key-->scroll down (faster)
Clr/Home---->H key-->Goto first file in selected list
Shift Clr/Home---->L key-->Goto last file in selected list

Why did I do this? I just like keeping my fingers in the normal key range and hate searching around for the arrow keys. Likewise, the number keys are mapped into the Function Keys (0=F10, 1=F1, ..., 9=F9).

3.2 TAGGING STuff:

Tagged files are a fundamental feature of hdscan and its usage. To tag a file, simply scroll to the file you want and press the 't' key. You will see a '*' appear in a little scrolling region next to the file name and the file window will scroll to the next file (so you can keep pressing 't' to select a bunch of files.) As each file is Tagged, you will see the total Tagged size increase in the TOTAL TAGGED window. To untag a file, just use the 'u' key. To untag all files, type 'ALT-U'. Note that directories will also appear in the file selection window (they have a 'D' next to them). I don't allow tagging of directories so you can't delete them, but they are useful for reference to see what all is in a directory (and when you are checking out protections, modify dates, etc).

3.3 SEARCHING AND SELECTING STuff:

3.3.1 Searching for files

Most of the time, you will probably just want to search out a few files for tagging and won't want to scroll over all 5000 or so files in the database. To accomplish this, if you press the 's' key, you will be prompted for a <13 character string to search for (you can enter stuff like .doc, .c, junk, etc but no * or ? wildcards are supported...to be truthful, I never even had any requests for wildcards.) The 's' key option will make its selection from all available files. If you just want to perform a selection from the currently selected subset of files, the 'S' key should be used instead. This will

allow you to easily narrow in on a set of file names. Both options will allow you to enter just an asterisk (*) if you want to just see Tagged files, and entering only a carriage return will reselect everything.

3.3.2 Selecting/Searching for a directory

There are also times when you might only want to select the files in one disk or directory. To do so, pressing the TAB key will turn the DISK: window into a little scrolling region, allowing you to use the arrow keys to quickly scroll to the appropriate disk. If you have a lot of disks to scroll past, you can just type '/' or '\' followed by a few characters that are in the disk name to search forwards or backwards respectively in the disk tree. When you have the disk you want in the PATH: window, you can either press the TAB key again (to select all the files in the currently selected disk) or the right arrow key to move the scrolling region over into the PATH: window. Moving into the PATH: window will let you further refine your selection down to the exact directory on the disk in question. Again, once you have gotten to the correct directory, pressing the TAB key will select all files in that directory, on that disk. If there are no files in the directory you are trying to select, then DISKSCAN will inform you so and let you select another directory.

There is also another method that allows disk selection. If you press the N or P keys, the disk in the database that is Next/Previous to the one in the DISK: window will be selected. This is a useful way of swinging through disks checking sizes or whatever. Note that in both selection methods, my definition of the next disk in a tree is based on the next alphabetically sorted path for that disk. This will be more apparent once you use the program.

3.4 DANGEROUS STuff (Copy/Erase all Tagged files...and more):

Once you have everything that you need Tagged, pressing the 'm' or 'M' keys will invoke the mass file copy routine. Selecting 'M' will copy files while preserving the original file dates and attributes, whereas the 'm' key will create a file with the current date. This option will prompt you for the destination path and allow you to copy all Tagged files (with or without an interactive query on each file). Once copied, the '*' next to a file name will become a '#' to show that the copy was successful. If you later want to re-tag the '#' files, possibly for mass erase ('E' key), you can do so by pressing the 'ALT-T' keys.

3.5 VISUAL STuff (Viewing and Dumping files):

One nice feature of DISKSCAN is that by pressing the 'v' key, you can view the file that you are currently 'ON' in the file window. The view option does a character by character analysis of the file, just displaying the ASCII printable characters on the screen, so it can be used for looking for strings in a binary file. Note that because I chose to allow looking at binary files, I also turned off highlighting, tabbing, and formfeeds that sometimes appear in files. If you want to get a HEX dump, press the 'V' key and you will get a page by page listing of your file in both HEX and ASCII. You can edit

the file you are currently pointing at in the scroll window by pressing the '*' key (shift 8). 'vi', or whatever you designated as your favorite editor in the DISKSCAN.KEY file, will be loaded, read in the file, allow you to edit and save the file, and then return you to DISKSCAN when you are done.

3.6 ARC STuff:

To get a verbose listing of the contents of an ARC file, move to the file you want to look at and then press the = key. While the verbose listing is being displayed, you can press the CTRL-S key to pause the listing and the CTRL-Q key to continue the listing in case it is longer than one screenful.

To add all Tagged files to an ARC file, just hit the + key. You will be asked for a path name, so just type in the full path to the file you want everything arc'ed to. Note that this name can be either an existing file name or it can be a new name. The Tagged files will then be ARC'ed together. Please note that the current implementation of 'add to ARC' is horribly inefficient...but it works.

3.7 SOMEWHAT NEAT STuff:

3.7.1 Sorting files (Only in the Professional version)

DISKSCAN allows you to sort all selected files (don't confuse Tagged with selected...selected files are simply everything you can currently scroll past in the file name window, whereas Tagged files are those you have Tagged with the T key for some future purpose.) By pressing the 'o' key, you will tell DISKSCAN that you wish to sort the selected files. DISKSCAN will prompt you for the sort key (i.e. file size, name, date, protections, etc) and then ask whether you want to see them in ascending or descending order). Since you can sort files over a whole file system, a sort by descending date is a useful way to tag what has changed since your last backup. A sort by ascending name is useful to find all those duplicate files. One note on sorting: I always fall back to RANDOM order upon a new selection by either search (S) or directory select (TAB). This provides the fastest response assuming you aren't always wanting to see the stuff sorted. If you really want files to be maintained in a particular order for viewing purposes, use the 'O' key to initiate your sort option. This will tell DISKSCAN to maintain that sort order throughout all subsequent file reselects...until another sort option is selected.

3.7.2 Comparing files (Only in the Professional Version)

An interesting feature in DISKSCAN is the ability to quickly compare files. You can use either the 'c' key or the 'C' key to perform this function. This option will use an internal routine to quickly ascertain that the files are the same or not. To perform a compare, move the cursor to one of the files you want to compare and press the 'c' or 'C' key. When you do so, a C will appear next to the file name and you will be prompted to go find another file to compare it against. When you have the scroll bar over the other file, press c or C again and the two files will be compared. For sanity's sake, my routine just shows the first 15 differences (byte locations and values) that the program finds. Note that you can do any number of file searches and directory matches in between selecting the first and second compare files.

3.8 POWERFUL STuff:

3.8.1 Doing things to a file

Because I got tired adding features to HDSCAN, and it was getting big, I decided to add one more feature. This is probably the most powerful feature (and the most confusing) as well. I decided to make the 0-9 keys into user definable keys. I have mentioned already how to create the DISKSCAN.KEY file, so will only mention here that to use the program you have assigned to the key, just press the appropriate key. If you forget what the user defined key assignments are, just press the 'I' key and you will be given a listing of the keys (along with a summary of disk space). This programmable key option uses the system() call, so you can even invoke commands that do redirection.

Note: I know it is confusing, but I decided to map the Function keys into the number keys (i.e. key 1=F1, 2=F2, ... , 0=F10) to keep things familiar for people using both the ST and Unix versions of HDSCAN.

3.8.2 Doing things to all Tagged files

Guess what you can also do with Tagged files? If you press the 'M' key after tagging a bunch of files, you will be prompted to press a command key (0-9). Yep, you guessed it. You can invoke any command upon all of the files that you have Tagged, one at a time. You can optionally have DISKSCAN pause after each file is 'processed' in this fashion or just let it run through all the files.

3.9 FINAL STuff:

Now, what have I missed? There are quite a few little options that I rarely use, but that people requested for some reason or other on the ST.

3.9.1 Renaming files

To rename a file, just hit the 'R' key and type in the new name. The file name you are currently selecting in the file window will be renamed.

3.9.2 Creating directories

To create a directory, just press the ~ key. You will be prompted for a directory name. You can type in the complete path of the directory you want created (i.e. C:\trb\PICTURES) or if you are already inside the directory you want to create the new dir in, just prefix the name of the new directory with a ~ character (i.e. if you see C:\trb up in the PATH window, just type:
~PICTURES
to achieve the same thing as typing C:\trb\PICTURES). This was originally intended for creating directories on the output media, so creating a directory will not cause that directory to be visible in the file selector window unless you do a rescan ('!' key).

3.9.3 Cleaning up the disk order

To beautify ('B' key) the order that files are presented, I added an option that goes through and groups all files into disk order, rather than the RANDOM order that you will see files in upon running DISKSCAN. The RANDOM order is

actually the same order that you added the disks to the diskscan database and may be preferred by some people (access is faster). After you get used to viewing files via using the match, directory select, and sort options, you will probably never even bother using the 'B' key. Note that if you invoke DISKSCAN with a -b option from a shell you will get this option by default.

3.9.4 eXtra STuff (Output Options)

I have added three print options to DISKSCAN. The 1.0 version has a Short output option which puts the disk name and a columnized listing of all the files in each disk out to a file. You can then edit this file and/or print it out at your leasure. The 2.0 version has a database dump option (printing out information of the form "DISK:full_path_name/file_name size date") to a file as well as a Long output option which columnizes the name, size, and date in a two across fashion. In all cases, only the selected set of files are saved to the output file and the sort order is preserved in the 2.0 version (which is handy if you want a printout of all your pascal files sorted by reverse date but still grouped in disk order...)

3.9.5 WARNING!

Some words of caution before you continue. First, while copying, DISKSCAN does not check to see if the destination file already exists...it will just overwrite the destination file. Second, I don't do any bounds checking on input, so if you feel you must have long directory names that require you to type in over the scroll window graphics, go ahead. You can't hurt anything that pressing the ? key twice won't solve. I know that I should really go in and prevent that from happening, but this program was designed not to be restrictive and should allow you to use it in ways I haven't planned for yet (planning for the unplanned?) Finally, be careful about using the 'e' key. If you tag some files in one directory, then do a search for some other files and tag some of them, be aware that the previously Tagged files will also get erased (unless you un-tagged them of course). Just because you can't see the file any more in your currently selected subset of the disk does not mean it isn't Tagged (that will be obvious, actually, if you look at the total Tagged window). If you are at all unsure, just use the select option to select all Tagged files prior to deleting them ('s' and then search for '*'). Happy computing...

4.0 SUMMARY OF COMMANDS:

Sure, now that I have told you about all the commands I condense everything into one paragraph:

(~) key: Create a directory
! key: Rescan the disk in the scan drive (default drive is A)
key: Invoke selected program (i.e. the file under the cursor)
+ key: Add Tagged files to an existing .arc file (or create a new one)
0-9 keys: Run external programs (defined in HDSCAN.KEY)
= key: Verbose Arc listing (peek at the names/sizes of ARC files)
HELP/? HELP (basically this info)/keymap info (i.e. command key bindings)
TAB key: Select files by disk (and by directory)

c keys: Compare two files. Tricky on big files unless on the same disk..
D key: Delete (kill) current disk from database.
e key: Erase all Tagged files (verification will be requested.)
G key: Globally run external programs on all tagged files.
h/l keys: Page up/down in the file selection window
H/L keys: Go to the Top/Bottom of the selected list of files
k/j keys: Scroll up/down in the file selection window
m/M keys: Mass copy all tagged files with new/preserved dates.
N/P keys: Move to the next/previous disk and select all files in it
o/O keys: Order (sort) the selected files (o=just for now, O=Always)
R key: Change name and/or attributes of file
s/S keys: Select match on all/Subset
t key: Tag a file
ALT u key: Retag all Copied files
u key: Untag a file
ALT u key: Untag all Tagged files
v key: View a file/strings-like
V key: View a file in HEX/ASCII
X key: eXtra STuff. This includes print options.

5.0 Currently known bugs/limitations:

1) Occasionally a file will show up in a directory on a floppy, but you
won't be able to access it from within DISKSCAN. This is a GEM/TOS bug
that I haven't gotten around to working out a safe fix for. I kept
hoping the new TOS would solve the problem. There is a workaround.
Open up the floppy from the desktop and then run DISKSCAN.
2) You can run some GEM programs from within DISKSCAN, but TOS seems to
get flaky if you do this too much...all I am doing is pexecs, so...

6.0 So you already have HDSCAN. What's New

This section is for those ST owners out there who already know all about
the old ST version of HDSCAN and thought they could skip over the docs for
DISKSCAN. The following 'HDSCAN'-like features are new for DISKSCAN:

1) More use of colors to move the eyes to the right spots on the screen. I
suppose everyone is going to bug me about picking the colors I did, but
I can always add that as a configurable option in a later release.
2) I got kind of hooked on the key configuration I set up for the Unix
version of HDSCAN, so I brought those definitions back into this version.
In most cases, the old keys you are used to will work, but things like the
h,j,k and l keys can be used in place of the Arrow key options, for
example. The only key that actually changed definition was the H)ex dump
key...it is now V)ex dump :-) and to view a file, you can still press v.
3) Would you believe Mass command key invokes? If you tag a bunch of files,
then press the M key you will be prompted for a command key (0-9). Yep,
you can now perform a user-definable command operation on all the tagged
files. I have come up with a lot of strange uses for this option.
4) Parameterized macros attached to the 0-9 keys...
5) Enhanced directory features. This includes searching while in the
disk selection mode and the ability to cycle through the disks

one at a time with the N and P keys while in file selection mode.

7.0 FINALLY, THE END IS NEAR:

Again, have fun with the program. It is meant to be a utility that is used from time to time. It was never intended to be used as a shell, although you may link into a shell from within it if you have enough memory (DISKSCAN is a memory hog). I should also remind everyone again that this is NOT a public domain program. It is copyrighted and I am distributing it free in the hopes that I can build up interest in the professional version. While it is true that I wrote the program to satisfy a need of my own, I did put a lot more work into making it into something that everyone else could use and understand. I have switched to this method of distribution because shareware didn't work and my brief exposure to marketting a product via magazine ads made me realize that I couldn't afford to do it and still sell programs for $20 or less (which is all I really think anyone should ever have to pay for a general purpose utility).

If there is a change in DISKSCAN you feel that the world must have, send me a note and I will try to integrate it into a future version. If you want to buy the production version, just send in $20 (U.S. dollars). If you don't think it is worth that, even a letter is appreciated if you find the program useful (or if it would be useful if it had a certain feature, for that matter).

In article <147@bdt.UUCP> david@bdt.UUCP (David Beckemeyer) writes:

>Copyright notice or no copyright notice, in my experience it's very
>difficult to enforce outside the US and Canada.

Well, it should not be so. And there is a very big difference between
USA and Canada with respect to copyright, as Canada has signed the
international Berner convention on copyright, and USA has not.
Most of Europe has ratified the Berner convention too, so it should
be as easy to get your rights respected in Germany (BRD) as in Canada.

In Berner Union countries it is not required to have a copyright notice
on your work, to enjoy copyright protection.

>There was a company in Germany that started to produce MT C-Shell with
>their own manual, diskettes, and packaging. German authorities informed
>me that this is perfectly *legal* in Germany, becuase you can't copyright
>anything but "works of art"; and software isn't in this category.

Well, it is the common theory within Berner Union experts that
software *is* protected by the international copyright convention,
this has been discussed a lot of times in these circles, and in
other international legal circles discussion the protection of
software rights.

The problem is that there have not been that many cases to settle the
situation. I know that there is proposal to the Danish copyright
law which explicitely states software as covered by copyright,
and they justify this as just a codification of current state.

To enjoy copyright protection, the "work of art" should be "published"
and the work should be of a certain "work height" to be intellectual
property worth being protected. It is assumed that almost all
software has the sufficient intelligence put into it for it to be
protected. Not protected is very trivial programs which everybody
with just a common knowledge of the issue could write. I think
things like AT&T's "true" program will fall in this category,
and even more complicated things too:-). I do not think the
software you mentioned falls into this category.

>The only illegal act would be if they were claiming they were selling
>"original" factory goods. As long as they say they are selling copies,
>it's legal in Germany. Even if they are breaking the law, all we could
>do is attempt to get a court order to force them to stop selling.

It should be enough to go to the police. But then it seems that the police did not know the legal status. Did you talk to a copyright lawyer?

>The best solution turned out to be getting a real legit. distributor
>in Germany; and let the competition of a supported product for less
>money shut them down (which it did, I think). I don't know if the
>legal issues above are "correct", but that's what happened to us.

When was it?

Due to a hefty amount of requests for this info I will post it:

Megabyte Computers
109 W. Bay Area Blvd
Webster TX 77598

Ph. 713-338-2231

This 14Mhz board is gem compatible and I have not heard of ANYTHING that does not run on it. Of course, they have not tried everything.

The reason that is so compatible is that it does not change the way the ST does anything, it just changes the speed of the whole system by using a faster chip than the 8 mhz one. That is what I got from the phone conversation anyway.

Would seem tobe the reason that the menu bar lockout in Word Perfect
and the alt\cntl\shift won't work in K-Switch or the Supra hard drive
over ride won't work also. Any way to alter this by way of a small program
that would be run in the AUTO folder at boot up?

Just in case you want to know the definitive story:

``The notice consists of three parts: the symbol (c), the year in
which the [work] is published, and the name of the copyright owner.
(The [U.S.] law permits the word *Copyright* or the abbreviation
Copr. to be used instead of C-in-a-circle symbol, but since the
symbol suits the requirements of the Universal Copyright Convention,
to which the United States and most European contries belong, it is
greatly to be preferred. There is no point in using both symbol and
word, as some publishers do.) In addition, most publishers add to
the notice the phrase ``All rights reserved,'' as this expression
assures protection for the book under the Buenoes Aires Convention,
to which the United States and most Latin American countries belong.

``For any work published with a notice of copyright the law requires
the copyright holder to send two copies to the Copyright Office . . .
The deposit is to made within three months of publication, and no fee
is required. Failure to make the required deposit does not forfeit
rights under the law . . .''

A few points:

1. I am not sure whether (c) is really a valid substitute for C-in-a-circle,
so this may be a good reason to use ``Copyright (c) 1988 . . .'' Maybe
an expert on the International Copyright Convention could fill us in.
Is it even clear whether this is usable for software?

2. Since there is no penalty for not sending in the copies (unless, as the
quote says later, specifically asked to by the Registar of Copyrights),
there is no real reason to bother. Perhaps a lawyer could tell use why
they bother making something ``illegal'' but giving it no penalty.

3. You can get extra protection in an infringement suit by registering
your work when sending copies if you want to.

4. Posting an item to the net or any other public forum would seem to meet
the legal definition of ``publishing,'' but again perhaps more of an
expert could fill us in.

5. I have directed followups to comp.misc. I can't see what any of this
has to do with operating systems, and the distribution is surely too
wide.

Laser C that will show up in the stores will not have this bug. Also this bug will only show up when you have around 15,000 initialized "things" That is a lot of typing and will probably only affect a minute number of people. (That number is also per file. not the overall number per program)

Michel @ megamax.

Anyone who would like a reply to their mail sent to me needs to give a uucp path. The mailer on our system is weird. Either that or give me a tel. number and I'll give you a call.

2099. Laser C from Megamax

Newsgroup: comp.sys.atari.st
Date: 1988-02-28 19:48:13 UTC
From: cs4l3ah@maccs.UUCP
Message-ID: <1024@maccs.UUCP>
Source record: 254100

-----line eater food -----------

I just received my Laser C upgrade from Megamax (minus docs).
It is great! BUT I can't run it!

It absolutely requires a one megabyte machine. With all the resident
programs flushed it still won't compile a small sized C source file.

Also, It accesses drive A: for some reason every time it starts even
when installed on the hard disk - forcing me to wait while it times out.

They obviously tested this thing on a 1040ST with floppy only.

If someone at Megamax is listening :

Please produce a version that will run with 512K.
OR: revise the old shell and editor to include env. vars, the new editor
and interfaces to the linker/compiler.

Does anyone out there know how to install an environment variable? Are
the env var.s standard in the ST OS? If I can get these variables installed
I can at least run the new version of the Laser C compiler with the
old shell - pity since the new dev shell really is fantastic.

Yah, yah, I know get the d*&m thing upgraded to 1 meg.. :-)

Thanks,
Richard Werezak

Been a while (my modem died). But here it is, the promiced documentation
for mx2.

The spacing is as the author wrote it.

------------------- cut on dotted line ---------------------------------

PAGE - 1 - MX2 Multitasking Kernel

```
*************************************************************************
* SHAREWARE *
* To register send $20.00 to *
* *
* Fred Brooks *
* 4145 44ST #5 *
* San Diego CA 92105 *
* *
* You will receive the complete Modula-2 source, *
* updates and programming examples for JSM2 and TDI. *
* *
* MX2 V1.0.0 A multitasking and multiuser *
* environment for ATARI ST. *
* Written using TDI Modula-2 3.01a Compiler *
* For TOS Versions 11/20 1985 and 04/22/87 *
* Other Versions may not run correctly. *
* *
*************************************************************************
```

Intro: MX2 is a multitasking environment to aid in program development
for the ATARI ST. It was developed in Modula-2 but can be used
with any language such as C, BASIC, or PASCAL. Suggested system
minimum requirements are 1 MEG of memory with a double-sided
disk drive. A hard disk drive will greatly improve system
performance.

MX2 Multitasking Kernel

PAGE - 2 - MX2 Multitasking Kernel

NOTES:

I have tuned this kernel for use with the GULAM shell. I have
had no problems using it exempt with the TE communications command.
It locks up my background xmodem routines if it is used.

MX2 Multitasking Kernel

PAGE - 3 - MX2 Multitasking Kernel

SYSTEM GENERATION:

The MX2.INF file contains the system generation parameters.
It is an ASCII files that can be edited with the UE editor in
GULAM or any ASCII editor This files allows you to change the
default system boot parameters
If this file does not exist the default values are:
numeric values are in decimal

Init Command : IP CLI.PRG
System Memory : 32000
Alt Program HOTKEY : 3276800
Normal Mouse HOTKEY : 3211264
Cursor Mouse HOTKEY : 3014656
Reboot HOTKEY : 1245184
Reserved Memory : 32000

Initialisation command is normally used to load the SHELL
program. The CLI.PRG enables GULAM.PRG to multitask then loads
the program. If the program is exited the kernel will respawn
the SHELL. To change the program change to IP "name of program"

System memory is the size of the memory reserved by MX2 to
allocate for it's internal data structures. The default size
should be adequate for 7 MX2 processes with workspaces of 2K.

Reserved memory is the size of the memory that will be released
to the alternate program is available memory drops below
the size of the reserved memory.

MX2 Multitasking Kernel

PAGE - 4 - MX2 Multitasking Kernel

INTERFACE LIBRARIES:

The SYSCALL module is the standard interface for user programs
to the MX2 Multitasking system. It includes functions to starting
ending and controling concurrent processes. The TDILIB contains
the TDI MODULA-2 3.01a libraries and JSM2LIB contains the
JEFFERSON SOFTWARE MODULA-2 1.00 libraries. I will include a
portable C library as soon as I can find out how the convert
the code over.

MX2 Multitasking Kernel

PAGE - 5 - MX2 Multitasking Kernel

COMMUNICATIONS:

Also included is a no frills communications program.
COM.TOS without options sets the AUX port to 1200BPS.
COM.TOS # "where # is a number" will set the AUX port to
the speed according to the table.
0 = 300BPS

1 = 1200BPS
2 = 2400BPS
4 = 4800BPS
9 = 9600BPS
H = 19200BPS
Use the [Undo] key to exit back to the CLI.

MX2 Multitasking Kernel

PAGE - 6 - MX2 Multitasking Kernel

MX2 HOTKEYS:

Hotkeys for several functions are included. These are the default
keys they can be changed in the MX2.INF file.

ALT m = Load and switch to second CLI or program, the screen and status
of the first cli is saved. If used after the second
CLI has been loaded this command will switch back and
forth between the two. It is recommended that this
command only be used in TOS programs. If a you only press
RETURN after the program name prompt the CLI.PRG will
automatically be loaded.

ALT r = REBOOT computer. This is the same as pressing the
reset button.

MX2 Multitasking Kernel

PAGE - 7 - MX2 Multitasking Kernel

BACKGROUND TIMER:

The background timer CRON has been implemented. When MX2
is started the file CRONTAB is read into memory. CRONTAB lists
the start time and frequency of the MX2 command on that line to
be executed. To stop the CRON from running the entries in the
CRONTAB file you can rename it or after the the CLI is running
issue the "SYS CRON OFF" command to stop.

All times are in minutes. You may have up to 16 entries in the
CRONTAB file. The format of the CRONTAB file is.

Start Time Frequency Command
0 60 SYS BP DUMMY.PRG

midnight every hour run the DUMMY.PRG in background

MX2 Multitasking Kernel

PAGE - 8 - MX2 Multitasking Kernel

NETWORKING:

MX2 has a low speed disk sharing network built in the kernel.
The network uses the midi port to allow a second ST that

is also running MX2 to use the remote ST's drives. The remote
drives can be used just like your local drives but they will of
course be slower because of the transfer of the data through the
midi ports. The remote drives will start as the second drive ID
after the last drive that you have on the local ST. For example
if you have drives A,B,C,D,E,F then the remote drives will be
| | | | | |
H,I,J,K,L,M To use the C drive on the remote
system simply use the J: drive on the CLI. Be sure to cross connect
the midi cables ie... the MIDI out to the MIDI in on the other ST
and vice verse.
midi in ___ ___ midi in
ST 1 \/ ST 2
midi out ___/___ midi out

The MX2NET.PRG is a standalone network driver that runs from
the DESKTOP or another GEM program. It can be installed in an
AUTO folder or run from the DESKTOP. It will allow disk sharing
between ST's that are not both using the MX2 environment.

MX2 Multitasking Kernel

PAGE - 9 - MX2 Multitasking Kernel

MISC:

The condition of the CapsLock is indicated by an asterisk in
the upper right corner.

MX2 Multitasking Kernel

PAGE - 10 - MX2 Multitasking Kernel

Known Bugs, Fixes and Improvements:

V1.0.0 The spooler will not work with networked files.

V1.0.0 MX2.ACC accessory will allow MX2 to multitask in some GEM
programs. The TDI editor will allow MX2 to switch when running
this accessory.

V1.0.0 Some programs will start up ok but on exit cause the system to
crash. Probably caused by Term code. If I used Term(0) to end
a program in MODULA-2 this will cause the problem. Solution:
just let the program END without any GEMDOS Term command.

MX2 Multitasking Kernel

PAGE - 11 - MX2 Multitasking Kernel

MX2 Commands:
() mandatory parameter, [] optional parameter
priories range from 1 to 10
Always use SYS before all commands if run from
the CLI.

MX2 Multitasking Kernel

PAGE - 12 - MX2 Multitasking Kernel

Program Commands:

IP : Run Interactive Program. This is normally only used to
run the mx2 CLI when the kernel first boots. The kernel
will respawn the program if it terminates or exits.
USAGE : IP [priority] (filename) [command],
SYS IP [priority] (filename) [command]

BP : Run Background Program.
Background programs use the same I/O vectors as the process
that started it.
USAGE : BP [priority] (filename) [command],
SYS BP [priority] (filename) [command]

FP : Run Foreground Program.
Foreground programs always use the normal ST I/O vectors.
It's use would be to run programs that use the ST screen and
keyboard from processes that have been redirected to the
RS232 port or MIDI port.
USAGE : FP [priority] (filename) [command],
SYS FP [priority] (filename) [command]

MX2 Multitasking Kernel

PAGE - 13 - MX2 Multitasking Kernel

XMODEM COMMANDS:

XR : Receive an XMODEM file from remote computer.
USAGE : XR (filename), SYS XR (filename)
This command will start a background process to
download a file. If the download is complete a single
bell will sound at the console. If the download
aborted for some reason four bells will sound.

XT : Send an XMODEM file to a remote computer.
USAGE : XT (filename), SYS XT (filename)
This command will start a background process to
upload a file. If the upload is complete a single
bell will sound at the console. If the upload
aborted for some reason four bells will sound.

XA : Abort XMODEM transfers.
USAGE : XA, SYS XA
This command will abort all xmodem background
processes.

XS : XMODEM Status.
USAGE : XS, SYS XS
This command will display the current status of a
xmodem up or download.

XCRC : XMODEM crc MODE.
USAGE : XCRC, SYS XCRC
This command will set xmodem transfers to
Cyclic Redundancy Code error detection method.

XCKS : XMODEM checksum MODE.
USAGE : XCKS, SYS XCKS
This command will set xmodem transfers to
Checksum error detection method.

MX2 Multitasking Kernel

PAGE - 14 - MX2 Multitasking Kernel

PROCESS PRIORITY:

NICE : Change Process Priority.
USAGE : NICE (priority) [pid], SYS NICE (priority) [pid]
If NICE is called without a pid the current process
will be used.

MX2 Multitasking Kernel

PAGE - 15 - MX2 Multitasking Kernel

PROCESS COMMANDS:

HP : Halt Process.
USAGE : HP (pid), SYS HP (pid)
Pid is the process id number of the process you
wish to Halt. To start up a halted process use
the WP command. The HP command takes a process out
of the ready list and removes it from the CPU but
NOT from memory.

WP : Wakeup Process.
USAGE : WP (pid), SYS WP (pid)
Pid is the process id number of the halted process
you wish to Wakeup. The WP command puts the process
back into the ready list to be run in it's time
slot.

PID : Process Identifier.
USAGE : PID, SYS PID
Returns the Process Identifier of the current
process.

MX2 Multitasking Kernel

PAGE - 16 - MX2 Multitasking Kernel

SPOOLER COMMANDS:

SP : Background file Spooler.
USAGE : SP (filename), SYS SP (filename)
puts file in process list to be printed. Unless

the path in included it will use the current dir.

ASP : Abort Spool.
USAGE : ASP, SYS ASP
Will terminated the current spool process and
allow the next to start if present.

MX2 Multitasking Kernel

PAGE - 17 - MX2 Multitasking Kernel

PROCESS STATUS COMMANDS:

PS : Process Status.
USAGE : PS, SYS PS
Display description of all system processes.

PSL : Process Status Log.
USAGE : PSL [filename], SYS PSL [filename]
Write to SYS.LOG file the description of all
system processes. If a filename is given the
description will be written to that file if
possible or else it will default back to SYS.LOG.

ZS : Zombie Process Status.
USAGE : ZS, SYS ZS
Display description of all inactive system
processes.

ZSL : Zombie Process Status Log.
USAGE : ZSL [filename], SYS ZSL [filename]
Write to SYS.LOG file the description of all
inactive system processes. If a filename is
given the description will be written to that file if
possible or else it will default back to SYS.LOG.

MX2 Multitasking Kernel

PAGE - 18 - MX2 Multitasking Kernel

BACKGROUND TIMER COMMANDS:

CRON : Background Scheduler Timer.
USAGE : SYS CRON [ON OFF]
CRON with no options will display the current
timer table entries. CRON OFF disables the timer.
CRON ON read the CRONTAB file, reloads the timer
table then enables the timer.

MX2 Multitasking Kernel

PAGE - 19 - MX2 Multitasking Kernel

NETWORK COMMANDS:

NETOFF : Turn off MX2 network.
USAGE : NETOFF, SYS NETOFF

NETON : Turn on MX2 network.
USAGE : NETON, SYS NETON

MX2 Multitasking Kernel

PAGE - 20 - MX2 Multitasking Kernel

MX2 UTILITY PROGRAMS:

SP.TOS Same as the MX2 SP command except it runs
directly from the CLI.

PS.PRG Same as the MX2 PS command except it runs
directly from the CLI.

ZS.PRG Same as the MX2 ZS command except it runs
directly from the CLI.

REDIR.PRG Program to redirect screen and keyboard I/O to
the RS232 port.

COM.TOS Program to communicate thru the RS232.

SUBMIT.TOS [cmd] Program to send string on the command line to the
keyboard buffer.
SUBMITA.TOS [cmd] send string to RS232 buffer.

MX2.ACC Desk accessory to allow MX2 to multitask in
some GEM programs.

MX2 Multitasking Kernel

PAGE - 21 - MX2 Multitasking Kernel

SYS.PRG USAGE:

The SYS.PRG reads it's command line and submits the command the
the MX2 kernel. It's use to to give MX2 commands from another
program such at GULAM. Example "SYS BP LOOP.PRG" will load
and run LOOP.PRG as a background process. All MX2 commands
can be used. To get a process status enter "SYS PS"

MX2 Multitasking Kernel

PAGE - 22 - MX2 Multitasking Kernel

DESIGN and IMPLEMENTATION:

MX2 is not a CLI shell. It provides a platform for system
services for a CLI or programs. When MX2 boots it looks for
CLI.PRG in its directory. If it exists it will be run as an
Interactive Process as the command shell.

These are examples for use of the amulti kernel make use of the
trap 15 interface. This makes it possible to use kernel services
in other languages that allow inline assembly or code.

```
#1 format for commands that require a string
pea buffer
move.w #8,-(sp) function number for sp
trap #15
add #6,sp
.
buffer:
.dc.b 'test.mod',0
```

```
format for commands that need only function #
#2 move.w #11,-(sp) function number for pid
trap #15 display pid on stdout
add #2,sp
result in D0
```

```
#3 format for vfork
move.l #subaddress,-(sp) subroutine address
move.l #2000,-(sp) workspace size
move.w #23,-(sp) function number for vfork of subroutine
trap #15
add #10,sp
```

MX2 Multitasking Kernel

PAGE - 23 - MX2 Multitasking Kernel

DESIGN and IMPLEMENTATION:

function name trap type

```
0 off #2
1 st #2
2 ps #2
3 stl #1
4 psl #1
5 ip #1
6 bp #1

```

20 xs #2
21 xcrc #2
22 xcks #2
23 vfork #3 runs a subroutine as a
concurrent process. A
RTS terminates the process.
24 info #2 returns a pointer the
current process descriptor
in D0.
25 rpid #2 return the process id number
in D0.
26 tick #2 force context switch

MX2 Multitasking Kernel

PAGE - 24 - MX2 Multitasking Kernel

SETUP:

Unarc the files and place them all in the same dir. You
MUST have a copy of GULAM.PRG for the SHELL.
Run MX2.PRG and the CLI.PRG will load and be ready for input.
I have included a few batch files to set up and to help run a
CLI in background to the RS232 port.

Please let me know of any fixes that you come up with or
improvements.

HOME PHONE 619-584-0281 San Diego CA. 5PM-10PM Please.

Source record: 254103

In article <994@sbcs.sunysb.edu> lean@sbcs.sunysb.edu (Lean L. Loh) writes:
>It's silly to post a 50K uuencoded thing which is preceded by 2 lines saying
>it's a blah, blah, blah.
> ... etc, etc, gripe gripe gripe.

A) I posted the contents of the .arc file several days prior to posting the .uue. B) The topic had been discussed to a small extent on the net already. C) I specified that it was the sources, and demo, for an alternate File Selector routine. D) I didn't write it, so I had no more information to pass on.

Please don't take this as a personal flame, Lean. You had valid concerns, but I feel obliged to defend myself.

New Topic:
==========

About the unkind treatment of James Turner (ex-moderator of the source and binary groups) lately: perhaps some of the criticism has stemmed from the fact that many students are used to having a great deal of time to spend perusing the net each day. People working full-time have an entirely different concept of free time. It is a cherished thing, especially in a workforce in which one is often expected to put in 50+ hour weeks with no overtime pay. I've had a few co-op work-terms in such an environment, and even though I was not nearly as busy as some of my co-workers, I found that I had very little time or energy to fool around on my computer at home in the evenings. Probably James has even less time than I had. And he has recently started a new job, so the last thing he wants to do is to get caught spending time uploading Atari ST sources and binaries to the net during work hours. Good way to make a first impression.

I for one wish to thank James for the work he did; his only failure was in delaying too long the decision to drop a duty that he evidently had little or no time to perform. But when he was more active, he did a first-rate job. Thanks, James!

2105. Re: Laser C

Newsgroup: comp.sys.atari.st
Date: 1988-02-29 00:41:34 UTC
From: braner@batcomputer.tn.cornell.edu
Message-ID: <3882@batcomputer.tn.cornell.edu>
Source record: 254105

[]

I finally sat down and tried out the new Laser C (Megamax 2.0). First I
installed it on the hard disk. One main file refused to copy at first,
I had to try several times. Bad diskette? The graphical shell will take
getting used to but seems rather nice: much better than the desktop, and
includes some commmand-line features. A main point of frustration for
me is that command lines must be terminated by ENTER, not RETURN. I guess
that's for safety, since one can enter a command line from an editor window.
But in the "STDIO" window pressing RETURN is just second nature to me.
On the other hand, one can go back (even scroll the window back!) to a former
command, put the cursor at the end of the line, and press ENTER. One can
even select (by dragging the mouse) a block of lines, press return, and
(ta-da!) it is like a shell script (alas without conditionals, etc).

The shell includes installation of system tools as resident in RAM, and a
disk cache with write-through optional separately for each tool. The
compiler and linker work very fast if they are in RAM and their output
is NOT write-through. That's how the 4-second turn-around time is achieved.
(That's right: if you edit a small program in an editor window, and press
Control-R, you get the output of the program in about 4 seconds!)
One can opt for saving of the source before compilation, just in case.
When one quits from the shell all non-deleted not-written-through
output is flushed to disk. But first the "cache management" dialog
is activated, where one can decide delete some files (e.g., *.o) from
the cache so they will NOT be written to disk.

A bit of snooping with the supplied disassembler shows:

- block initialized data: no more element-by element copying
when one codes "static int a[] = {1,2,3,4,5,6,7,8};".

- FP ops (as in "double a,b,c; a=b+c;") are done like this:
move b-->fpreg0 (two move.l's)
pea c
pea fpreg0
jsr doubleadd <--- no more dispatcher nonsense
(push opcode, call central...)

The very fast turnaround time means simple benchmarks are very easy to do.
Here are some DOUBLE FP times, in MICROSECONDS (millionths of a second):

dabs 60 <--- they don't call it fabs :-(
add/sub 160
mul 250
div 320

sqrt 1800
exp 2300
log 2800

(These times include a complete C statement including assignment of the results, e.g., "double a,b,c; a=b+c;".) I believe these are pretty good results for SW FP on an 8MHz 68000. I havn't tried the Savage benchmark right now but when Megamax sent me a prerelease of the new FP package it was faster---and more accurate---than Absoft FORTRAN, which fits with the above results.

Other things I noticed in my first session with Laser C:

- The supplied "cat" utility displays text with the newlines missing, i.e., as one long line. This is true even for text files created with their editor!

- My utility "MORE.TTP" does not work right when invoked from inside the shell (using "tos more filename"). It reports a "TOS error", meaning the file was not found. I suspect the shell passes command-line args to the program in a nonstandard way: MORE.TTP was written in AL and examines the basepage directly. Other .TTP programs I tried (e.g., my version of microEMACS) read the args fine. Any ideas?

- Text in the shell's windows is drawn and scrolled VERY fast, especially given that these are standard GEM windows (at least they appear to be, with scroll bars, resizeable, etc).

- When I run microEMACS from inside the shell, it reads long text files much more slowly than it does when invoked from the desktop. E.g., a 25K C source file takes about 3 seconds outside, 6 seconds inside the Laser C shell. The only reason I can think of is that the cache is not very fast and gets in the way. (Those times are from the hard disk.)

#include <std.disclaimer>

- Moshe Braner

PS: trying to run UNITERM from INSIDE the Laser C shell resulted in a crash that was too much even for that shell's exception-trapping facilities!

>>
>> No, what we ALL need is what should have been there all along: A
>>*DIRECT* pipeline to Atari's top management.
> ^^
>
> HA! HA! HA! HA!
Ha ha ha is right. Should have been there all along is a relative
thing. It would be nice for us, the consumers. But it would be a royal
pain in the a*s for the upper management at Atari.

I can just see a lot of people harping at Tramiel and Co. in the early
days, when Tramiel had dumped a large amount of funds into what seemed to
be a financial black hole to everyone else - a company millions of dollars
in debt, not to mention the company itself split into three, non-cooperating
spheres of influence: home computers, home gaming systems and coin-op
systems.

The argument about any PUBLIC service having things like direct
feeds to upper management is correct, unfortunately Atari Corp., while
a public corporation stock-ownership-wise, is still largely owned and oper-
ated by one family.

Granted, Atari has pulled off some major public relations disasters
("Moses PromiseLAN"? I mean, in the immortal words of Ms. RIvers, "CAN WE
TALK?") but they have delivered the company from bankruptcy to a state of
at least semi-coherency.

This is not meant to curb the current flame war, no, my ST lies
broken and near death in my bedroom back in the dorm. I am not precisely
sure what is wrong with it, but it looks as if a motherboard swap (if the
old $95 deal is still on) is the only financially feasible way of 'repairing'
it. C'est la vie.

Tell you what though. If Atari wants to get involved in "other
markets" as Mr. Dodd implies with the '030 box and the Abaq transputer,
they better get a real attitude about customer support, and fast. Or there
possibly will be no more Atari to flame after they dump a couple hundred
million in a transputer project.

Think I will just buy a new drive for my 800 and forget the ST
(half :-)

2108. SX212 fun 'n games

Newsgroup: comp.sys.atari.st
Date: 1988-02-29 01:47:55 UTC
From: cfchiesa@bsu-cs.UUCP
Message-ID: <2229@bsu-cs.UUCP>
Source record: 254108
Cross-posted to: comp.sys.atari.8bit,comp.sys.atari.st

In response to the recent fever of SX212 praise and wonderment, I gave in and went out and bought one yesterday, intending to UNPLUG my existing modem (which talked to my Atari through an 850 Interface and so-called "standard" RS232C cable) and plug in the SX212 instead. I had it on good authority (this net) that you could indeed do this, with no hassles.

I got the modem for about $99 (came to $103.95 with the 5% sales tax here in Indiana), brought it home, unplugged the old modem, plugged in the SX212, and threw the switch. Nothing happened. It didn't work. The SX212 would indeed talk to my Atari - accept Hayes-like commands, respond with "OK", and all that. It did NOT, however, even so much as ATTEMPT to talk to the PHONE LINE! It just sat there and did NOTHING. I was devastated.

Before collapsing in cardiac arrest, however, I checked the documentation, and was astounded to find that this very problem was in fact covered in the section on "Troubleshooting." The problem, it turned out, was that the "DTR" (Data Terminal Ready) line of the RS232C connection was NOT PRESENT. Oh. I tried a few more 850 Express! commands, but nothing made any difference vis-a-vis bringing up the DTR signal. Finally, checking the cable itself, I found that not only was there no signal on the DTR pin of the cable, there wasn't even a PIN at the proper location (pin 20 of the 25-pin) in the connectors! My old modems apparently didn't mind, but the SX212 can't deal with it. So for the past day and a half I've been searching for ways to fix MY cable, replacing pin(s), connector(s), and/or whatever else I could find. Radio Shack (forgive me; I was desperate) had an RS232C cable and a "serial port adaptor" for ITS line of equipment, which had the correct number of pins on both ends, but after bringing it home I found that the particular pinouts were wrong.

Finally, good ol' Dave P. (aegnor@bsu-cs) stopped in, and suggested that perhaps the oft-mentioned "Club II BBS" would have an alternate R: handler that would let me say goodbye to the RS232C and 850 arrangement, and simply connect the SX212 directly to the SIO port. We quickly logged onto the Net, got the Club II BBS phone number, dialed into it, found "RVERT212" in the File Section, downloaded it -- and, to make a long story just a little shorter, HERE I AM, TALKING TO YOU VIA SX212, "RVERT212" R: handler, and the KERMIT65 (minus contained R: handler) that was posted here a few months back!

It WORKS, gang! Go out and get 'em NOW!

This thing is BEAUTIFUL, in operation AND in appearance. Even my non-computerholic girlfriend calls it "the squirt" because "it's so cute!"

Anyway, that's my tale, which had an unexpectedly happy ending. I'd like to thank John Dunning for porting Kermit65 in the first place, and whomever it was (I forget, sorry) who posted the Club II BBS info here! The entire face

of my telecomputing experience has been changed beyond recognition, much for the better, due to you guys. Have a happy!

2109. Re: Lyco Computer

Newsgroup: comp.sys.atari.st
Date: 1988-02-29 04:36:57 UTC
From: Mark_H_Brandwein@cup.portal.com
Message-ID: <3560@cup.portal.com>
Source record: 254109

Concerning Lyco Computer: I have ordered from them on two occasions, once back in 1980, when I purchased my first 800. The service was fast and flawless. However, when I ordered my 520ST from them in 1986, they said they were in stock and would be shipped tomorrow. Two weeks later, I had called them to locate my order.. the girl said there were no monitors in stock, and were waiting for ME to call to ask me if I was interested in receiving the keybd, drive, etc... and they would send the monitor when it came in (old ST with TV modulator!). I replied "of course" and got the ST in 10 days, the monitor a week and a half after that. Other friends I know who have dealt with Lyco say the same, that Lyco will tell you "OK", and let you sit and wait, when they really are out of what you ordered,or something else. I recommend Electronics One in Ohio. I ordered a 1020 printer/plotter from them while I was stationed in Korea... it arrived ten days after mailed the letter! Now THAT is good service!

2110. Sources Wanted, Rogue & Moria

Newsgroup: comp.sys.atari.st
Date: 1988-02-29 13:49:49 UTC
From: wsl@erc3bc.UUCP
Message-ID: <19@erc3bc.UUCP>
Source record: 254110
Cross-posted to: rec.games.rogue,comp.sys.atari.st

I am looking for the sources to Advanced Rogue Version 5.8 could somebody mail me a copy? Thanks a lot.

Also, I have a hardcopy of the sources for a Version of MORIA. These sources are written in VAX PASCAL. Does anybody know if there are sources available for UNIX/C (or any C for that matter). I would like to try to port the ROGUE and/or MORIA sources to my ATARI ST.

Again thanks a lot in advance.

2111. Atari Advertising Idea

Newsgroup: comp.sys.atari.st
Date: 1988-02-29 14:12:05 UTC
From: rkolker@netxcom.UUCP
Message-ID: <690@netxcom.UUCP>
Source record: 254111

Okay folks at Atari (I know you're out there) here's an idea for ST advertising.

In all of the interminable up-close-and-personal features ABC ran during the Olympics, there was one on Debi Thomas, figure skater and pre-med student using her computer. Well, look at that, it's an Atari ST (looks like a 1040).

Now, this would have been better if Debi had won the gold, but she is a role model, not only as a skater but as a student, and if you want to show the ST as a serious computer, maybe sell a few to college students, she sounds like a perfect spokesperson to me...and she already chose the machine!

Just an idea.

Line-A was used because, well, Apple used it, and it was there. Line-F was used as an optimization (two-byte JSRs so the AES would fit into ROM), and is in no way related to the way the ST is "defined" to the outside world.

Questions about what IS defined on the ST should probably be directed to the guy in the hotseat, Mr. Good. Since the final technical documentation is over TWO YEARS LATE (!) I'd expect it to be a priority item now. There is no substitute for good documentation -- and the ST just doesn't have any yet.

> This probably explains why the megas come with a 68000 rather than a 68020.

Nope. The ST is pretty stuck in the mud with respect to the 68000, but for different reasons. Moving to a 68020 will be painful for EVERYONE.

[]

So other people also have problems with the Laser C upgrade disks?
I must add to my story that the almost-unreadable disk I got was
apparently used before: some scratches on the shutter. My theory
is that (since they asked us to send in the original disks) they
reused the old disks. I don't think that's very bad (remember:
we only paid $20 for the upgrade, including the (still to arrive)
new manual) but I wish they (1) used _my_ old disks (they were not
scratched...) and (2) did a better verify on the copies...

- Moshe Braner

Addendum to my preview of Laser C: The editor (and the whole shell)
are very distinctly Mac-ish, for better or worse. E.g., when choosing
system tools to install in RAM upon launch I feel like I'm in the Mac's
Font/DA Mover, what with two lists of items and an [>>add>>] button, etc.
Also, the file selector boxes that pop up when you click on "compile"
or "run other programs" in the "execute" menu are NOT the (ugh, tfoo!)
standard GEM version but a much nicer original version. Better than
the Mac's, too.

I wrote a letter to Leonard Tramiel. The letter apparenly went to
/dev/null - I never got a reply (and I mentioned that I was a registered
developer). And now I find that there is a blacklist and I may be on it.
I hope that the Atari people on the net somehow manage to make the
Tramiels understand that blacklisting developers is not a good way
of promoting a business. Its not a good tenet of war to make your
allies into enemies. (and Jack believes business is war?)

> Commnet Systems

The ST color monitor is an ANALOG RGB monitor; it WILL NOT work
work with a CGA or EGA card. It's timing matches NTSC specs; voltage
levels are 1 volt peak-to-peak. It should work with a PGA adaptor
(though you might need some voltage level conversion resistors) and
might work with a VGA card. It also should work any Amiga.

The best place I know of for cables is Practical Solutions in Arizona.
(I think that's the name; they make the "Monitor Master").

2117. RAM expansion chips, etc.

Newsgroup: comp.sys.atari.st
Date: 1988-02-29 17:36:07 UTC
From: chaz_heritage.WGC1RX@XEROX.COM
Message-ID: <880229-093722-1392@Xerox>
Source record: 254117

Does anybody know the CORRECT specification of extra RAM chips for the ST?

I tried to sort this out with a UK supplier who is doing RAM expansion boards for a (relatively) sensible sum - they quote 120 UK pounds for the board (and they say it ought to be more, but their boss made a mistake with the dollar exchange rate) and sundry astronomical sums for the chips.

When I called them in the morning the chips were 256K DRAMs ("sorry, don't know what sort") and they were 18 UK pounds each. This was both technically and financially incorrect. In the afternoon they were 1M DRAMs ("sorry, still don't know what sort") and they were 28 UK pounds each. This means, for 4M worth (what I wanted) a total of over 1K UK pounds the lot. The guy claimed that this was because there was an earthquake in Japan and the ground opened up and swallowed the chip factory, the uninsured loss of which was being passed on to the customer.

I don't know if there's any truth in this, but I'm quite certain advantage of the mistake on the board price I can get the DRAMs somewhere else for more sensible money (hell, for 1K pounds I could nearly get an ST4 anyway).

The only 1M DRAM I could find in the dreaded RS Components catalogue were Toshiba TC511000P-10. These are 100ns devices, and I understand that I don't need any faster than 150ns. Anyway, these things cost about 25 UK pounds from RS (but that's inevitable with them). The board people couldn't tell me the device organisation but I guess it's 1M x 1bit.

Can anybody sort this out for me? What I'd like to know is:

1 Device spec (part number, manufacturer, access time, organisation, number of pins, even...). I've heard that certain manufacturers devices, such as Samsung, won't work at all.

2 Is it true that the factory is now on its way to California by the scenic route? If so, why are we expected to pay for it? Or is someone out there sitting on a huge pile of these things, spreading rumour and profiteering?

3 What about the power supply? My 520STFM sits there quietly smouldering as it is - the left-hand side of the vent slots gets nicely warm. All those RAMs are going to want some power - can the internal supply handle an extra 2A max. (64mA refresh) or will it finally brew up? Calculations based on Toshiba devices as above.

4 The guy I spoke to seemed to think that the price ought to go down, rather than up ("we're not making anything on this, you know..."). How much do you folks Stateside pay for this sort of device? Just how badly am I going to get burned? It might be worth asking someone visiting the US to buy them for me there - any East Coast people have a suggested supplier?

5 Is this really worth doing at all, or should I just stop jerking off and get an ST4? I can't really afford it, but I'd consider this course rather than drastically marginalising the design of the 520STFM.

Hope somebody actually reads this far.

Regards,

Chaz

"You do, huh?"

2118. Laser C bug reports/notes

Newsgroup: comp.sys.atari.st
Date: 1988-02-29 18:11:14 UTC
From: dclemans@mntgfx.mentor.com
Message-ID: <1988Feb29.101120.12013@mntgfx.mentor.com>
Source record: 254118

This is what I've seen so far trying to port over a large working
package from Megamax C version 1 to Megamax Laser C:

1. Generation of bad code

in a routine like

```
foo()
{
.
.
.
if (...)
{
if (...)
return;
}
#ifdef bar
bar is not defined, so this block goes away
#endif
}
```

at the end of the routine there was a garbled branch instruction,
that the outer "if" tried to jump into the middle of. The instruction
to restore register variables was missing. This was relatively
easy to find with the traceback facilities of the shell.

presumably what happened was that the generated code originally was
bne ret
ret: restore regs
unlink
rts
and then the optimizer came along and didn't collapse the branch correctly

2. libraries/linker

ar seems to create libraries without a "ranlib" index by default. However
if the linker sees a library without a "ranlib" index it seems to go into
an infinite loop.

once a library has a "ranlib" index ar intermittently has problems updating
members in the library; it sometimes says that the library has a bad format.
This doesn't happen consistently so I don't know what causes it.

3. cc

cc supports a -l switch to reference libraries, and a LIBPATH environment variable to help it find libraries. The ability to use this facility would be extremely useful, as what I'm trying to do is large enough that I have trouble fitting it into the 127 max command line lengths of make.

However cc seems to process all -l switches first, and scans those libraries first before any other files are looked at (presumably because of how cc builds the command line for the ld). Since there are no undefined references yet, it never loads anything from those libraries, thus the -l switch to cc is TOTALLY and COMPLETELY USELESS! "-l" switches should signal that the library is searched in the order that the switches appear in the argument list; if a "-l" switch appears after a filename, the library must be searched AFTER the object for that filename is loaded.

If you reference libraries via a real pathname, everything works fine.

4. utilities

Presumably "cp" is a command to copy a file; experimenting with it definitely makes it look like it wants to copy a file. However it gives the file "copy" a read-only attribute. With that attribute you can't modify, edit, delete, etc. any "copied" file within the shell environment.

*** I may find more bugs; the package is still having problems

5. miscellaneous notes

(These aren't bug reports...)

If there's going to be any further problem in getting the real documentation, could someone at Megamax on what the libx library is? From the header file it looks interesting.

It looks like the compiler now has only 8 significant characters, vs. 10 characters in V1.

The "overlay" keyword is gone

By default you get a 8KB stack; to get more declare and initialize a long integer _stksize with the desired stack size.

Please post a summary to the Net!!! I've got Megamax C-compiler and
do some C programming, but its all "general" programs. I don't know
enough about the ST to incorporate windows, mouse, disk access,
graphics, sound, checking for things like the correct screen resolution
etc from within my C-programs. Cursor control via escape
sequences I know about. Some good reference books might do the trick.

No you don't... You want a bomb to kill the running program, back to
the interpreter, so the programmer can correct the problem. Or,
you should install your own bomb handler (as most interpreters better
than ST BASIC do).

> isatty(fh)
> int fh;
> {
> if(fh>2)
> return(0);
> else
> return(1);
> }
>
> Thanks
>
> Peter

There is a better isatty. It uses the property of tty's that seeking
always returns zero, while seeking forward in a file file either returns
an error code or a new (nonzero) offset in the file.

This code works for "standard" handles which have been redirected to
files or other tty's, and for "nonstandard" handles which are files or
dup'ed copies of tty handles.

This function returns EIHNDL if the handle is invalid, 0 if it's a
file, or 1 if it's a tty.

```
#define ERANGE -64L
#define EIHNDL -37L

isatty(h)
int h;
{
int rc;
long oldloc, seekval;

oldloc = Fseek(h,0L,1); /* seek zero bytes from current loc */
if (seekval = Fseek(h,1L,1)) /* try to seek ahead one byte */
if (seekval > 0 ||
seekval == ERANGE)
```

```
rc = 0; /* file, not a tty */
else
rc = EIHNDL; /* EIHNDL, for instance: invalid handle */
else
rc = 1;
Fseek(h,oldloc,0); /* seek back to original location */
return rc; /* return true or false. */
}
```

2122. Re: Problems w/uue files at ATARINET (UH-INFO@UHUPVM1.BITNET)

Newsgroup: comp.sys.atari.st
Date: 1988-02-29 20:11:48 UTC
From: uace0@uhnix2.UUCP
Message-ID: <500@uhnix2.UUCP>
Source record: 254122

I must take exception to the comments about files not working from ATARINET.
ALL programs have been tested before being sent to ATARINET. My usual path
is to send the file to the UNIX, uudecode it, dearc it, and if it dearcs ok,
then I assume the files are ok. I also take ALL new programs and place them
on a DISK OF THE MONTH for my users' group, so I know they work on the ST, too.
If it then dearcs ok, I re-uuencode it (if it doesn't have a character at the
end of each line, to prevent space truncation), or leave it as is.

The problem is REALLY brain-damaged gateways that do BAD translations of
characters. If you have gotten UUX UUE from ATARINET, this takes care of
almost all problems. The problem is definitely not ATARINET!

2123. Laser C; more notes

Newsgroup: comp.sys.atari.st
Date: 1988-02-29 20:39:46 UTC
From: dclemans@mntgfx.mentor.com
Message-ID: <1988Feb29.123953.12156@mntgfx.mentor.com>
Source record: 254123

One further note/bug report:

Exception catching from the Laser C shell seems to work fine with GEM programs. However it doesn't necessarily return to the shell correctly. If menu access is blocked via a wind_update call, the shell doesn't seem to unblock it; thus if you try to return to the shell you have to reboot anyway because you can't access any menus.

Ideally this could be checked for automatically; possibly there could be an "unblock" shell built-in that would put things right.

>he is still waiting for word...

Typical Atari practice. Say anything and do nothing. It appears that
there are even members of the staff with this specific responsibility (they
don't seem to anything else). Job description: "Get somebody excited by
promising the moon, then just forget about it."

In other words STALL 'em if they can't take a joke.

With all this flaming, I have to give Atari some credit. Their direct
developer support isn't that bad (only $300 for a dev. kit).

I think Thomas Zerucha makes makes a good point when he says that nobody
knows what the ST can really do (outside the ST insiders) and that's where
Atari has really screwed up. They expect the small-time developers to fund
the software development *and* all the marketing too. Atari just isn't
pulling enough of the load; small companies don't have the resources
to do it by themselves; and large companies aren't going to do it for
Atari until they (Atari) can show that they're serious.

C'mon Atari show us you mean business. Action not words.

This may have been hashed around before, but I never saw the final verdict,
so please excuse me if this is "old news".

Just exactly how will RAM memory be managed on the ST under MINIX? On the
PC I remember MINIX uses 64K offset addressing? With absoulte addressing
on the Atari some things must be different no?
1) does this mean a "fixup" table a la TOS and PC-DOS?
2) what about swaping:
2a) a fixed "text" area, and a swap on each context switch?
(don't laugh I've seen this proposed on the ST).
2b) no swapping
2c) the "fixups" are remembered so the program can be
relocated at run-time?
2d) other
3) what about dynamic memory (e.g. malloc):
3a) Is there one heap, many, or something else?
3b) can it be swapped/relocated/shared/overlayed?
3c) sbrk causes a swap (like V7)
3d) fragmentation problems?

4) protection scheme?
4a) none
4b) software integrity/ownership tests?
4c) other

I was wondering whether any one out there has
the secret for importing NEO (low res) type
pictures into Publishing Partner. I am using
IMG Scan to scan pics at low res, because I have
a color monitor, then I've saved the data as both NEO
and Degas. When either are loaded into PP they
look like garbage. I've also tried reading these
into Degas Elite, saved as PI2, as recommended
in the PP manual. The results are better but
still a long ways from being anything I would
want to look at. If anyone out there has any
ideas please let me know. Thank you.

>anything but "works of art"; and software isn't in this category.
This is positively wrong. It is not (!) legal to copy the work of
someone else.
In fact, it's illegal to copy software at all. You may make up to seven
backup copies of software you buyed, but you must not give any away (for
the case of fire or the like..).

All brain-work is protected under the law of copyright (german:
Uhrheberrecht). Even if somebody deletes the copyright message or
patches the version number (happened with WordStar years ago).
> Even if they are breaking the law, all we could
>do is attempt to get a court order to force them to stop selling.
Wrong again. That would only be the first thing.
Even if they would give the copies away for free they _could_ go to jail...

If you ask the right peaople the right question you will get the desired
answer.

I would call it the lesser of two evils rather than damage. Without
these hardwired os calls, lots of memory would have been wasted on
implementing a portable os that really had nowhere to go. Without
these memory maps there may never have been a home computer (read
home vid-game machine) revolution.
And yes, the effects linger on much to the chagrin of many CIS
departments across the globe :-)

I want to add to Roy Good's call for using only documented system calls. I think we need more adherence to the "rules". But we also need clearer rules and bug free functions (or at least documented bugs). Of all the 'new' machines, the ST has the worst and most difficult to find manuals.
Compare the photocopied ST devpack docs to the AppleIIGS docs (the hardcover texts at Waldenbooks). Perhaps if we could get better documentation, we would adhere more closely to the official calls.

(by we, I mean programmers in general. I'm stuck with Pascal so I'm not doing many system jumps;-)

I was under the impression that Migraph had a PostScript driver for EasyDraw since last fall. I've been using the HP Laserjet driver, so I hadn't looked into it. My advisor recently got interested in EasyDraw, and said he would buy it if he could get a PostScript driver. So he called Migraph.
The person he talked to said that the PS driver was almost ready, but it had been put on indefinite hold and they didn't know when it would be released.
That seems pretty bizarre to me. I haven't received a newsletter from Migraph for a couple of months. I'm curious as to what they are up to...

From: FXDDR@ALASKA.BITNET
Message-ID: <8803011823.AA28598@ucbvax.Berkeley.EDU>
Source record: 254137

Well, give credit where it is due. After all the grouching about Atari, here's something positive. After calling around trying to get information about bus timing in the ST and getting nowhere, I mailed a request to Cindy Claveran and just got an 8-page document called "Mega ST Series Internal Expansion Bus Documentation" dated 2 October 1987. It doesn't have timing diagrams but it does have some interesting tidbits, for example "Atari has set aside the addresses C00000 through CFFFFF, FF0000 through FF7FFF, and FFFE00 through FFFFFD for use by outside developers." Nice to know, since my pet project just fits in 7FFF, and I was going to arbitrarily stick it at 400000.

I still don't know how much time GLUE and MMU eat out of the available access time or what the DMA chip timing looks like, but I guess I can just assume RAM faster than 150ns will work. We'll see what happens. There's always the logic analyzer and other medieval tools of torture.

With memory getting expensive, perhaps instead of an external RAM disk an internal RAM disk in the C00000-CFFFFF slot would be more attractive...all that would take is the RAM and a DRAM controller.

I wonder why Atari gives such a small amount of address space to developers. They barely use 5 of the 16 MB now. Do they really need to reserve 10 MB of space for their own future use? Oh well..."I got mine."

>
>
> Matt Singer
> Commnet Systems

The ST color monitor is an ANALOG RGB monitor; it WILL NOT work
work with a CGA or EGA card. It's timing matches NTSC specs; voltage
levels are 1 volt peak-to-peak. It should work with a PGA adaptor
(though you might need some voltage level conversion resistors) and
might work with a VGA card. It also should work any Amiga.

The best place I know of for cables is Practical Solutions in Arizona.
(I think that's the name; they make the "Monitor Master").

dgc
********************************************************************************

VGA would be fine.... I need to replace a CGA/Amdek 310 combination
and would just prefer to not have to buy both a video card and a monitor.

In article <16@erc3bc.UUCP>, wsl@erc3bc.UUCP writes:
> (2) Is there now (or will be in the near future) a SQL based database
> available for the ST?

Well, Atari announced a while ago that they would be selling one of the BIG Unix-type SQL databases for the ST *running Idris*. Idris, if you haven't heard of it, is a "Unix-clone" o.s. I think the database was either Ingres or Oracle, both of which are well-regarded products in the Unix minicomputer world.

> (3) Is pc-ditto a worthwhile product?

Yes, but it does have some limitations. The current version only runs with the color monitor. They have announced a new version that will support monochrome; it may already be out. PC-Ditto does a very good job of mimicking the IBM PC on the ST, but it is fairly slow at a lot of operations.

> (4) Would it be practical to run an MS-DOS DB package on the ST using
> pc-ditto?

If you will be using the database heavily, you'd be better off either finding one for the ST, or buying a cheap IBM clone. Besides, the only SQL database for MS-DOS I know of (Oracle) require a 286 machine with lots of extended (protected-mode) memory. Maybe a cheap AT-clone?

> I hope someone will post a response. Any and all are much appreciated.

2145. SUPRA Code for read/write DMA port

Newsgroup: comp.sys.atari.st
Date: 1988-03-01 15:56:12 UTC
From: crash@calgary.UUCP
Message-ID: <1414@vaxb.calgary.UUCP>
Source record: 254145

Hi,

I've gone through the Supra DMA code quite throroughly, and
used it. One possible bug is with their use of the "dma" variable.
First off thats a bad name for it. It is used for two purposes, to
select one of eight dma devices, and then to select one of eight
units on that device. Normally, no matter what device you select,
you'll want unit zero (it being first). However if you use the Supra
code, and select device 1, you'll get unit 1 (and so on). This is
because they reuse "dma" for unit selection.

I have re-documented their code, probably handy for those with
out developers doc. I have also made some code to make all work.
Anyone who wants let me know.

M. Braner- got your mail, replied but it suffers from this sq.sq.com
thing.

2146. Re: ETRNL2 and new roms (Supra hdboot override)

Newsgroup: comp.sys.atari.st
Date: 1988-03-01 16:20:35 UTC
From: dclemans@mntgfx.mentor.com
Message-ID: <1988Mar1.082038.13440@mntgfx.mentor.com>
Source record: 254146

The Supra hard drive boot override does work with the new ROM's;
timing just becomes critical. You can't keep the keys held down
through the whole boot sequence, because the state gets cleared
during system initialization before the driver is called.

Basically you have to judge when initialization is over (relatively
easy on monochrome displays; harder on color systems) and hit
the keys then before the system starts reading boot sectors.

I'm selling my 1040 ST and goodies. It's all less than 1
year old, and all works. I'd like to sell it as a package,
but will set as individual items, if necessary.

Hardware (Manuals, most original packaging, all works <1 yr old):

1040 ST Mono Monitor
Color Monitor Deskcart (ROM-pack w/clock)
External Atari DS drive 30-40 disks
Supermodem 300-1200 modem Mousepad
Seikosha MP1300-AI printer Wico Joystick
(300cps printer w/tractor)

Asking $1500.00 for the hardware and manuals...

Software (All registered, with manuals/docs, etc):

GFA BASIC interpreter DEGAS Elite
Silent Service Leather Goddesses/Phobos
FLASH comm program Flight Sim II
F15 Strike Eagle Star Glider
High Roller ST Writer
Wishbringer Universe II

Asking $325.00

THIS IS NOT A RUMOUR!

It has been brought to my attention that Atari has been manufacturing
ST's with a most serious flaw over the last few months (time span is not
exactlly known). The problem is that some of the drives (Chinon) do not
reckonize a change is the write protect status properly (or at least
do not generate the required signal correctly). This means naturally
that the OS doesn't know when a disk has been changed and will happily
right old disk info to the new disk, which will naturally ruin the contents
of the disk.

The problem seems to effect the whole ST range (Mega and 1040), not all
are bad, but even Atari doesn't seem to know exactly the extent of
the problem.

To see if your ST has the problem, do the following:

a) get two NOT write protected disks
b) insert disk and open window
c) swap disks and press the Escape key

repeat c) a few times, if your ST always reads from disk each time
you press Escape, you don't have the problem otherwise:

DON'T USE YOUR ST ANYMORE!

and get the drive swapped!
(If you have a harddisk, you can naturally still use your computer.)

Isn't it nice how Atari alerted us about this problem as soon as they
noticed it :-/.

> This is a short little program I found on a local BBS:
>
> DiskFree V1.0 By Timothy Purves

I'm sure this works fine, and most of us know why Dfree is slow in the current (old and MEGA) ROMs, and I've already sped this code up in the new GEMDOS, but ...

If you start with a virgin hard disk, create a file on it, write 253K to it, and then do Dfree, you will see that *no* space has been used -- the 253K is not counted against you. This happens because until you close the file, the FAT sector (which you've filled with the one chain for this file) is still in a GEMDOS buffer, not on disk, and this utility (necessarily) subverts the GEMDOS buffers.

With that caveat aside, I'm sure this is a fine utility which people should use to speed up the Dfree operation ("Show Info" from the desktop when a disk drive icon is selected) until the new ROMs come out.

From article <1988Feb27.141030.26647@jarvis.csri.toronto.edu>,
by juancho@dgp.toronto.edu (John Buchanan):
> What can be done about accessing argv[0]. It would be nice to
> know what the name of the program running is. I have not seen any discussion
> about this.

Sorry, pal. The total discussion is, "It can't be done."

At least, not with the standard Pexec call. If you do something like
Beckmeyer and MWC do with the environment, you can pass whatever
information you like to the child process.

2153. Re: Ethernet protocols for the ST

Newsgroup: comp.sys.atari.st
Date: 1988-03-01 20:32:07 UTC
From: hase@netmbx.UUCP
Message-ID: <1467@netmbx.UUCP>
Source record: 254003

A german company, Biodata GmbH, offers two networks for the ST.
One is an Ethernet. They claim it will make the St a multiuser/-tasking
system.
Because of the rather high price we decided to look for something else.

Biodata can be contacted at Herrenweg 23 6272 Niederhausen/Ts. West
Germany.

I'm not connected with the company; not even as a customer.

Thank you.
That's what I wanted to read. (I gave up..).

When will we see the update (in Europe)? Will we get some kind of
"source" or hints to adapt TOS to homebrew hardware?
I just finished patching my ROMs to support the german 68020 board
PAK68. This patch was published in the ct, my favorite source of
ST-internals.
(I'm not happy with a working computer; I need a working soldering iron)

If K. B. is reading this. Hi!

I would like to thank the party responsible
for posting "levee" to the net. I would
like to encourage the fellow who redid
"stevie" round 2, to repost the src to the net
or send me a copy. Por favor. I missed it last time
and I can't find it anywhere.

Now to change the subject:

I noticed last night that the following inadvertant finger-goof
command adminstered from the Mark Williams shell on my atari
caused a great deal of havoc on my Mark Williams created ram disk:

mwsh> cp foofile e:\\

The first time I tried it, it "seemingly"
wiped out the hard disk. I ran "tuneup" on
the disk and tuneup did indeed find damage and
repair same. I then tried it again and tried it
on a floppy disk that I no longer loved (and studiously
avoided trying it on the hard disk...). This time
no apparent damage occured. All that happened was
that I got a file named "\". Now this made the
Mark Williams shell very unhappy. The desktop
showed the file as "noname" but showed.

mwsh> rm e:\\

worked. Curious. Now of course I tried it on my
pc-xt since of course we know that tos and dos
"have the same file system". All dos incantations
refused to permit "\\" as a filename. Good for dos.
Bad for tos. And here I thought that dealing with
the root directory on msdos was strange. Wrong.

This is another reason why K.B. is no longer using
her s.t. :->...

Source record: 254007

>>What books should I get/avoid? Abacus' line of ST books seem
>>interesting, but I've seen them flamed/praised, and I'm not so sure.

I was generally happy with books 2 and 3 (Internals, and GEM, can't remember the exact titles, sorry) but was quite disappointed with book 10, Introduction to MIDI.

For example, the book completely overlooks the important aspect of reading MIDI data from the synthesizer and time-stamping it so that you can send it out again properly (since MIDI itself contains no notion of duration codes - all it is are note-start and note-end commands, and the application software has to pause for the appropriate length of time between the start and end of the note.)

There was some sort of a throwaway line in the book like "We have decided to leave this aspect of MIDI programming up to you, so that you'll have something to do!" How about "We don't know how to do it!", if that's what you mean.

I think the book would be interesting to people who either know nothing at all about MIDI or who would like to see complete source code for a large application [it's a program for creating tunes by picking notes and time durations off of a menu - but I don't think it ever actually *reads* anything from the synthesizer] - but if you already know something about what the MIDI protocol is or are looking for discussion of some truly useful MIDI routines or programming techniques or advanced features of the MIDI standard, this is probably not the book for you. Buy "Keyboard" magazine instead, the monthly columns there are much more useful.

Using Debi Thomas as a spokesperson makes much too much sense (as well as being too expensive, eaven at bronze medal prices) for Atari to ever do.

This is aside from the misbegotten perception that the computing world is too lily white in the eyes of the ad executives to accept a person of color as a spokes person (ever wonder why there are no endorsements for the top black tennis players?).

2160. CD-ROM Development

Dear Atari ST Enthusiast:

Atari Corporation is pleased to annouce its new lost-cost (under $600 U.S.) CD-ROM player for use with its ST line of computers. Capable of reading both data and audio CDs, it connects directly to the ST's high-speed DMA bus. With the appropriate adapter card, the same CD-ROM player connects to IBM PCs and compatibles.

The ST series of computers is currently one of the best-selling computers in Europe, and is increasingly popular in the United States and Canada. With its high resolution display, friendly user interface, and the massive data storage of a CD-ROM player, the ST is an ideal low cost workstation.

A CD extended BIOS is being developed to provide ST applications with a standard interface to the CD-ROM player command set. In the future, Compact Disk Operating Systems will become available for emerging CD-ROM standards (such as High Sierra Group format).

Join us in supporting this revoluntionary product. The Atari CDAR504 OPTOFILE(tm) ROM player will be available for software development in March of 1988. Product release is scheduled for the second quarter of 1988. Note that there is no need to wait for CD-ROM players to arrive - application development and coding can start right now. We are interested in working with your company to introduce software to the large installed ST user base, and to insure compatibility of our products with yours. We also look forward to exploring possibilities in the MS-DOS world with our line of PC compatibles.

For more developer information about the Atari CD-ROM player, contact me at the address below.

This is TRUE, Atari Benelux (Holland, Belgium, Luxembourg) has loads of
replacement drives in stock. If you're dealer sold you an ST in the last
couple of weeks you can get a free replacement. However, the dealer has to
replace the drive himself.

>He was kidding of course ? (Wasn't he *PANIC* ?!?)

The OS for the ABAQ (if that's what it will be called: there are rumours that there is a Belgian company selling a games computer of the same name -)) will be HELIOS. This OS is being written by a british company called Perihelion. HELIOS is based on UNIX and on the distributed operating system Amoeba developed by A.S. Tanenbaum (you know: the one that did MINIX). Amoeba is a capability based distributed operating system, and HELIOS is too.

HELIOS is being written in C and transputer assembler NOT IN OCCAM. Most of the system calls of UNIX (V7 and some BSD) are equivalent, though more system calls are available to take advantage of the transputer architecture. Those system services include spawning processes on remote processors and inter process communication (IPC) using a message passing system. UNIX pipes are also (I think) implemented on top of the IPC, so pipes can be stretched across different computing nodes.

More info can be had from Perihelion or Atari UK (I don't have the addresses right now).

Source record: 254015

I have just recovered #60 from one of the BITNET servers, and I found out why, in that case and probably more generally, the file was truncated in the initial version sent to me. The problem was due to a lone period (.) at the beginning of a line!! Some USENET (i.e., UNIX) mailers use exactly *that* representation to terminate a message.

Is it possible to filter out such lines or precede them with "\" as do some other digests, before sending the digest out over the netwaves?

Thanks in advance,

Ralph P. Sobek

p.s. For contributors, would you please desist in putting such lines (".") into your communications.

From: ferneau@silver.bacs.indiana.edu
Message-ID: <11400011@silver>
Source record: 254021

I for one have to agree with Mr. Dickey. It seems that for quite
a while (at least one month) there have been no new postings to
the comp.(src/bin).atari.st newsgroups. If the newsgroup is
moderated, as it has been recently, the same situation might occur.

It is unfair that anyone on the net must rely on a single person to
take care of all the postings. It does seem fair, however, to set
down a few groundrules dealing with the situation. For instance,
every program should be arced, and uuencoded. The has been the
standard method in the past, and seems to work fairly well. Another
rule might be that all software be fairly well tested before it is posted
as we don't want to fill up the groups with garbage.

Please enter my vote for comp.(src/bin).atari.st becoming unmoderated.

>

AAAIIEEEGH!! You can't imagine how frustrating it is to put a lot of work into something and have it ignored. A few local developers spent a lot of time and effort creating a proposed standard for passing extended arguments, INCLUDING setting argv[0] properly. We then had the proposal reviewed and finally posted by Allan Pratt. It was not "officially" endorsed by Atari, but was recommended by Allan as a good way to handle the problems we were trying to address. A lengthy explaination about the method and sample source code was posted. And now I see "I have not seen any discussion about this." from a person who has been on the net for quite some time. Was this ignored? If there were problems with the proposal, I didn't see any comments, public or private, about it. What does a person need to do to get some feedback around here!

As a side note to Mark Williams Co. The problems with your method of passing extended argument list have been posted to the net in the past. Those have been addressed and resolved by this new scheme. Source code is available FREE for the asking. Please consider implementing this more flexible and less dangerous XARGS scheme.

Axiously awaiting a responce...

2175. Computer Mail Order, Inc. looooong shipping delay

Newsgroup: comp.sys.atari.st
Date: 1988-03-02 19:10:16 UTC
From: #FJMORA@WMMVS.BITNET
Message-ID: <8803022013.AA23316@ucbvax.Berkeley.EDU>
Source record: 254025

It seems that it is quite hard to buy a 1040 ST today.
I ordered an Atari 1040 plus some peripherals (modem, printer...)
from Computer Mail Order. It was Jan. 21, 1988. I paid with a cashier's
check to avoid the usual 4-week (!) check clearance delay.
Since they got my check, they keep promising to send it to me
"in a couple of weeks" with some "in 10 days" variations. Note that they
admitted my complaints on their 800 lines (a good point).

One week ago they promised to send it to me "next week, for sure". OK, I'm
waiting. I will tell you if they actually do it.
But can anyone tell me if CMO is normally so slow to ship you what
you paid for? To begin with, has any STist ever gotten anything from them ?

And some retailers complain that since Atari purchased Federated, they
dump all the STs they make into the Federated warehouse, and that
independant retailers just can't have STs. Is that true?

I feel that there are enough experienced ST material buyers on this
net to provide some useful purchase guidelines. Please give me your
opinion directly, or post it, and I will compile some retailer
statistics from this advice.

I have had no problems with the MWC routines themselves. But I have run out of memory (according to malloc()) while there was still plenty of memory left (prox 1/4Mb according to malloc(-1) or Malloc(-1)...it's been a while and I don't have my documentation here). This is due to the problem with the memory allocation scheme in TOS.

When malloc() is called, it calls Malloc to get a chunk of memory, from which it doles out the amount you requested. Subsequent malloc() calls give you more of the memory left from the previous Malloc or calls Malloc again as appropriate. After a small number of Malloc calls (20, 40?) you don't get any more.

>Just exactly how will RAM memory be managed on the ST under MINIX? On the
>PC I remember MINIX uses 64K offset addressing? With absoulte addressing
>on the Atari some things must be different no?
Indeed, 32 bit addresses and offsets. Inside the kernel and MM
clicks of 256 bytes are counted in 16 bit ints, so 24MB address
space. Physical and virtual addresses are identical.

> 1) does this mean a "fixup" table a la TOS and PC-DOS?
The GEMDOS-style relocation info is appended to the loadfile and
used during exec() to get the initial process image right.

> 2) what about swaping:
> 2a) a fixed "text" area, and a swap on each context switch?
> (don't laugh I've seen this proposed on the ST).
Indeed, an in-core process image swap, but not often.
In 99% of all cases this leads to 2 copies of the
process image per fork(), instead of 1 for a machine
with hardware relocation. Really!
In pathological cases (look at the MINIX test programs)
it takes many in-core swaps, but works. In practice, I
only foresee problems with terminal emulators. Slight
modifications to the code will be necessary for good
performance.

> 2b) no swapping
Then no fork().

> 2c) the "fixups" are remembered so the program can be
> relocated at run-time?
Only works for text and read-only data.

> 2d) other
> 3) what about dynamic memory (e.g. malloc):
> 3a) Is there one heap, many, or something else?
Fixed allocated area for stack and heap combined, like
for MINIX-PC. However, you can choose this area as big
as you like, as long as it fits in memory.

> 3b) can it be swapped/relocated/shared/overlayed?
I do not fully understand the question.

> 3c) sbrk causes a swap (like V7)
No.

> 3d) fragmentation problems?
Like MINIX-PC.

>
> 4) protection scheme?
> 4a) none
None, except that low core is protected in user mode.
(MM, FS, INIT and all user programs run in user mode).
This, and the many faults detected by the 68000 as
comapred to the 8088, give a reasonable protection
against programming errors, NULL pointers, stack
overflow and the like. So far I haven't seen a user
process crash the system, although it is rather easy
to create such a program on purpose.

> 4b) software integrity/ownership tests?
No.

> 4c) other
On process restart (when it is scheduled to run) a test
is made for orange or red stack violation.

>--

In the documentation that comes with MINIX-ST a more extensive
explanation of the implementation details is given, including a
description of the technique called 'shadowing' that is used to
implement fork() and exec() with full UNIX semantics.

>police did not know the legal status. Did you talk to a copyright
>lawyer?

My point was that "legal" or not, and regardless of any discussions
to that effect here or elsewhere: DON'T GET YOUR HOPES UP. The
authorites showed no desire to help a small software company in Oakland;
that includes both US and German authorites (police and Fed. agencies).

Any attempts to bring justice would have meant a law suit in German courts.
Several US and German copyright lawyers (supposedly some of the top ones
in the world) advised against doing anything (a strange practice for a
lawyer with nothing to lose) becuase it would be very costly, and the
outcome would at best be a court order to stop production, which the
company could simply ignore anyway since the police had better things
to do.

In other words: you can read and discuss laws and legalities all you want,
but in the *real world* all this means very little.

> What can be done about accessing argv[0]. It would be nice to
>know what the name of the program running is. I have not seen any discussion
>about this.
The ARGV= environment string (MWC format) supplies argv[0] through argc.
The first string after the ARGV= is argv[0], argv[1] is the second string,
and so on. Each string is separated by one NUL (zero byte). The list of
arguments is terminated with two NUL bytes (which marks the end of the env.)

The MWC msh shell and the Beckemeyer Development Micro C-Shell and MT C-Shell
command shells all support this "extended" argument passing convention.

The MWC startup code reads this env. and loads the args into the argv[]
array before calling main(). I don't think any of the other C compilers
do it yet. So programs written in MWC, when used with msh or csh will
have a valid argv[0]. I have a module that will read the env. for Alcyon
C. If anybody wants it send me mail. If I get a lot of requests, maybe
I'll post it. But without that, if you write your programs in another
C, or if you don't use msh or csh, then argv[0] will not be valid in
your programs.

>6 weeks which I think means that they are slipping their schedual a little.

This sounds like an excellent policy to me. Very fair, and it avoids the
"I'll wait for the new version" problem.

It is always nice to see companies support their customers.

I personally think it is a good idea for MW to hold off the release if
they have to. I'd rather have a well-tested version that is 100%
compatible and bug-free, than get a new version that breaks things
and needs another update 3-weeks later.

I know that the slipage (if there really is any) is not due to a
"vaporware" situation, like we have seen from others so many times before.
The software is all real; and I like the fact that MW is doing
extensive Beta testing before release.

You flame them for being late, and you flame them if it's not perfect
when it ships. What can one do?

[a line for the line eater]
Is there a more quantifiable method for testing for this problem? Since getting my Mega in December I've had many (6-8) disks go bad for no obvious reason. However, when I tried your swapped disk test, everything was okay. A couple other reasons could be: I was reorganizing my disks and mearly used some disks that hadn't been accessed in a long time (and might have gone bad anytime--North Dakota is a dusty place even with disk boxes); my disks might be just dirty. If either of these is the case, netland can't help me much. Another possibility is the RAM disk I started using when I got my Mega--it's a reconfigurable Ramdisk called Mikes Ram Disk, ver .95 from DClick software. I have suspected it because on the boot sector of one of my disks the word DCLICK appeared 6 or 7 bytes after the first--I wondered if the ram disk handler might have done something funny in memory (although maybe that disk was formatted with the DClick formatting program--would that have done it?). Another possibility is disk speed--I noticed my older external 314 was running at about 304 rpm--and it varied somewhat from that number. Could a sudden change in rpm be the cause of my woes? My last guess (other than the problem Simon mentioned) is that almost all of the disks that went bad were single-sided disks (if I could tell what they were at all)--could the mechanism in the Mega be pickier about formatting single-sided disks double sided? I'd sure appreciate any help netters could give me--having one or two seemingly good disks go suddenly bad (sometimes a bad sector, sometimes can't seem to read it at all--maybe the directory?) almost every week is discouraging.

Thanks,
Scott Udell

Perhaps RTX is doing something to fix this, but when I download in the background, I notice the freespace dropping each time I write a buffer to the disk, but the size stays at zero until file closure. There are some other odd things (ARC.TTP will move to the last byte and change the size) and if you hit reset, the allocated clusters will be left hanging, unattached to the file - and undeletable.

I don't know about that. I thought the internals book suffered from poor translation. It seemed that, in many cases, they got mixed up as to which chip was generating the signal and which was receiving it. Anybody else think that too? However, for educational purposes, the BIOS listing is interesting.

> for each cc in a make.

I can't say for sure, but I think the tools are probably exec'ing the programs they call directly, rather than using system(). MWC provides two library functions to make this somewhat easier, look up access() and path() in the Lexicon.

> 2) How does a typical mwc tool know that it has been called
> from a shell. When ever I use a tool it seems to assume that the
> program was run from the desktop and I have to press return.

I think there is an environment variable called CAMEFROM they are checking. Usual entries are desktop and msh, or something like that. The tools probably assume the worst (desktop) if they don't see anything.

> 3) How reliable are the malloc() and free() functions
> provided with MWC.

I haven't had any problems with them in 2.1.7, but I am (now) very careful to free() objects in the reverse order I malloc() them. As it turns out, this isn't that much of a limitation - I (NOW) always free blocks in the same routine that malloc()'s them. I've been stung by other compilers on other systems when I didn't do this.

> Has anyone attempted to use the Atari ST color monitor on a PC
> using either a CGA or EGA card? Was it successful? Can it be done?
> If so, where can I get the cables?

Nope, can't be done, at least not without some thrashing about with
the hardware. The ST uses an Analog RGB interface, this means the
computer tells the monitor how much of each color to use by putting
out different voltages on each of the three color lines.

The PC CGA adapter uses an RGBI interface; the I stands for intensity
(I think). The RGB values are always the same, the I dictates one of
two intensities or color sets.

The EGA adapter uses RGBII. As you can guess, this is similar to RGBI
but carries 4 bits of Intensity data by using two lines.

The big thing about "multi-sync" monitors is that they can be driven
from Analog RGB, RGBI, or RGBII type interfaces, and at varying
vertical sync rates.

2194. New release 1stw2ps V3.11

Newsgroup: comp.sys.atari.st
Date: 1988-03-03 07:28:00 UTC
From: U00170@HASARA5.BITNET
Message-ID: <8803030747.AA03743@ucbvax.Berkeley.EDU>
Source record: 254043

```
New release 1stw2ps Version 3.11 1 March 1988
=============================================

1stw2ps is a program that makes a postscript file from a 1stWord
or WordPlus file. The printout you will get looks much better than
that from any 24-pin, dot-matrix printer.

Spaces are adjusted so that each space occupies the same length on
a line.

New:V3.1 Several special characters are supported:
-- Output to RS-232 or Centronics.
-- Special header fontstyles.
-- Date and time inclusion.
-- Most (all?) bugs are fixed. I just forgot them
(e.g conditional pagebreaks bug).

New V3.11 -- copies option included.
-- head and footline bug fixed.
-- another conditional pagebreak bug fixed

Contents of (uue) archive :

2195. Juggler

Newsgroup: comp.sys.atari.st
Date: 1988-03-03 09:05:02 UTC
From: mclark@polyslo.UUCP
Message-ID: <1403@polyslo.UUCP>
Source record: 254045

In the March 1988 issue of ST Applications there is a blurb on a new Michtron program called The Juggler. It is supposed to work like Apple's Multi-Finder and switch between multiple GEM programs (all on the screen at once). Has anybody used this? I'm curious if it is really usable, how much memory it needs etc...

Thanks

Matt

2196. System vars, Linking

Newsgroup: comp.sys.atari.st
Date: 1988-03-03 10:10:48 UTC
From: neil@cs.hw.ac.uk
Message-ID: <1727@brahma.cs.hw.ac.uk>
Source record: 254046

We recently got Landon Dyers MADMAC assembler for the ST and with it is a
file of definitions (atari.s), a portion of which is shown below:- (risky?)

```
_sysbase = $4f2 ; -> base of OS
_shell_p = $4f6 ; -> global shell info
end_os = $4fa ; -> end of OS memory usage
exec_os = $4fe ; -> address of shell to exec on startup
scr_dump = $502 ; -> screen dump code
prv_lsto = $506 ; -> _lstostat()
prv_lst = $50a ; -> _lstout()
prv_auxo = $50e ; -> _auxostat()
prv_aux = $512 ; -> _auxout()
```

Question 1: Are the last five entries officially supported?
" 2: If so can we have some clear documention please?
(some seem fairly obvious but "Give us News before we abuse" :-)

These variables don't exist in the Bios Listing (Rev A) that came with the
dev-kit and lie in "No mans land" , but if Landon put them in a file for
distribution ...

Another issue:

If the Developers Kit is now being shipped with the Mark Williams C Compiler
instead of the Alcyon C Compiler where do we now stand with respect to link
formats? ALCYON C,AS68,LINK68,MADMAC & ALN use DRI/CPM68K object file formats
but MWC use their own (as does MEGAMAX, METACOMCO/GST etc grrr!).

MWC does comes with an assembler (with pretty some stange syntax eg. a $ not a
for immediate) and a utility to convert DRI to MW link format (one way
arrogance :-). To make a composite program with this mess one would have to:

Assemble with MADMAC
do a Partial link with ALN (I like the -i option)
Convert DRI to MWC object file (Assuming of course DRTOMW.PRG likes ALN)
Compile the C and link the final beast with MWC

to be able to get the full benefit from MADMAC,ALN & MWC.
Imagine trying this with a ram disk instead of a hard disk. :-(

And speaking of ram disks: If you know anything please help Mr. Franco
to fix ETERNAL2 to work with the new roms.

"I think all right thinking people in this country are sick and tired of being
told that ordinary decent people are fed up in this country with being sick and
tired. I'm certainly not and I'm sick and tired of being told that I am!"

>me from doing backups. He said it's floating around Genie, Compuserve,
>maybe some other places, but I haven't seen any mention of it here.

Yes, there is a 2.16, and even a 2.17. I haven't posted them to the net
because the changes are minor, and 2.18 will be a more significant change.
I'll post that when it's ready.

The only reason you may need 2.16 or 2.17 is bug fixes, for some very
obscure bugs. If you are having problems, mail me a disk, and I'll send
you a copy of 2.17. If you're looking for new features, you have to wait
for 2.18. It will allow you to set up your options in a data file, do an
install application on the data file type, and use it to launch TURTLE.
It will then come up with all your options set (including PATH and disk
number). That allows you to set up option data files for each different
backup sequence you have.

It also has the directory full bug fix, of course. It should hit the net
in a couple of weeks.

If you do happen to be encountering the RAMdisk directory full problem,
and can't get a backup done, mail me a disk:

I sent in my $100 to Perihelion to become a registered developer last year and so far have received only one thin manual - supposedly a system calls manual. I was so impressed with how close it was to unix that I kicked myself in the butt 12 times, saved up my pennies for a few months and went out and bought a Mac last week. The people who developed it may have had Unix at the back of their minds, but they certainly didn't set a goal for themselves of being source code compatable - in the way that MINIX is (with V7).

With Ataris track record for getting things out the door (I'm still waiting for the official Docs, blitter upgrade, rom fixes, PC add on box, a reasonable laser printer) and the way the workstation market looks today - strict unix compliance, competative prices and the dominance of a hand full of companies - I just don't see the world jumping over to the people who brought you pong. Nor do I see the major software houses jumping to support a computer which cannot provide a simple secure computer system - There is no hardware support for protecting memory space - the manual says something like - support for multi-tasking is an interesting exercise - Shudder.

Anyway, anyone who believes that perihelion will be a force in the workstation market any time this century, is welcome to contact me. Maybe we can transfer my developer status.

By the way - it was soooooooo nice to be able to walk into a bookstore and pick up $100 worth of books that told me everything that I want to know about the Mac. If I only could have done that a year ago for the ST (as was promised by Neil).

>machine AND THE Abaq system? :-)

Must be a newcommer - You are not going to see 68030 machines nor (I bet) an Abaq out of atari any time soon. (Soon in a Geologic sense). See the past history of PC clones, hardware upgrades, (Face it folks - the Mega is a 1040 in a new box - period), documentation and the like. Anything with a 68030 or a Transputer will put them in the same price range as the big boys and Atari will be crushed - they just have no concept of support and quality.

They should have stuck to the game market - that seems to be the direction that the ST is heading in anyway. Have you seen one of their Blessed Retailers lately - all games and very little else of substance. Even the cheerleading magazines are looking a little grey around the gills lately.

In addition to the one I mentione a month or so ago (something like 'Programming in C on the Atari ST' by someone like Compute!) there is the Sybex introduction to GEM programming (which is about GEM generally, and mentions both the ST and PC versions of it).

Also, I've just found (and bought -- I'll buy anything that looks like it might have good info) a new book:

Atari ST Application Programming
by Lawrence J Pollack and Eric J T Webber
Datatech Publications
Bantam Computer Books, 'The Programming Reference Library'

Cost me 22.95 UK pounds sterling. Imprinted 'in US $24.95, in Canada $29.95'. (So much for exchange rates.) ISBN 0-553-34397-1. Published Sep 87.

Only got it yesterday, so I'm not positive how good it is, but on the face of it (given the amount of scanning that can be reasonably done in a bookshop) it looks promising. Let you know if I change my mind.

Just how painful is it? I've been operating under this assumption for quite awhile -- people on the net have been saying that GEM/TOS would not work because of different sizes of exception frames, etc. A fellow here who didn't know any better put a 68020 in his 1040ST, and when I asked him about it, he said it works just fine. Runs all his TOS/GEM programs just fine. He said it even bombs normally.

Apparently he had to use some PAL's to do the trick, but since I'm not a hardware hacker, I couldn't say exactly what was involved. Certainly it's not for the faint of heart. This guy did his own 4M upgrade, too.

The speed isn't greater except for certain operations, he said (presumably the loop mode, instruction cache, and longword operations would be better). I assume that this is why Atari, et al, think the added expense is not worth the while (I'll agree), but what's the REAL story here?

Ok...the answer of the day... (and tomorrow, and tomorrow,...)
We are in the process of revising product test, release and support rules
for all products, and the good news is that future products such as the
68030 don't have a history.
The 68030 is mandated to comply with SVVS and X/OPEN requirements, and
implicitly with POSIX. A seasoned professional with many years experience
has been hired as UNIX Program Manager, working within my area, i.e.
Development Engineering. We are making other adjustments and hirings to
strengthen controls and support, as evidenced by my recent posting of
new job opportunities here at Atari on this very net (misc.jobs.offered).

I have almost 20 years in this business, entirely spent in system software
(and hardware) development and/or worldwide systems-level product support.
I am EXTREMELY sensitive to product quality and to post-release support.
Right now it's a question of finding people who are "pro-active" in those
areas to add to our existing capabilities. So if you know of anyone who
might be interested in such positions, get them to look at the job posting.

Roy J. Good
Product Development, Atari Corporation

Views expressed are my own. Atari may agree or disagree; they have the right.

2207. Symbol table?

Newsgroup: comp.sys.atari.st
Date: 1988-03-03 20:46:00 UTC

Message-ID: <19880303204623.4.JRD@GRACKLE.SCRC.Symbolics.COM>
Source record: 254157

While fixing the GNU linker so that it'd run on my ST, I had just finished the part that writes the symbol table into the executable file, when I realized that I couldn't think of anything that would use it once I'd written it (!) Is there anything that can make use of the symbol info in an executable?

Also, when one loads an executable, where in memory does the symbol info get loaded? Does the TPA point to it?

Thanks in advance for any info.

2208. MX2 suggestions

Newsgroup: comp.sys.atari.st

From: Jim McCabe JEMCCABE at MTUS5
To: INFO-ATARI16 at SCORE.STANFORD.EDU
Subject: MX2 suggestions

How about adding another GEMDOS function (there are a few spare function numbers, aren't there?) that is similar to pexec but lets the parent load other background processes. Sure, calling the SYS program (I have the early version of MX2 called AMULTI) will do the same thing but it's not as nice as having the loader also in memory. I ask that you use a GEMDOS call so that Pascal users like myself can still access it. (An XBIOS or BIOS call would work fine too.) (Unfortunately, Pascal folk can't just branch around in memory as easily as we'd like.)

With that improvement, lots of new programs could come out that take advantage of multitasking (like multiline BBS programs)! Of course, I'd be just as happy if RTX was released with specs too.

Since this discussion hasn't ended yet, I thought I'd bring up a few gotcha's regarding writing your own ^C and bomb handlers.

GEMDOS calls the Pterm handler with all files open, and it could happen at any instant in the code. Consider a recursive File Tree scanner that uses Fsetdta() and Fsfirst/Fsnext:

```
scan(pattern, mask)
char *patter;
int mask;
{
DMABUFFER dbuf, *olddma;

/* remember callers DTA buffer */
olddma = Fgetdta();
/* Set DTA buffer for this scan */
Fsetdma(dbuf);
if (Fsfirst(pattern, mask) == 0) {
do {
/* see if found a directory */
if (isdirectory(dbuf))
scan(pattern, mask);
else
/* process file */
} while (Fsnext() == 0);
}
/* reset DTA */
Fsetdta(olddma);
}
```

If a bomb or ^C occurs at recursion level N, the dta pointer points to memory on the stack (the auto dbuf variable). Clearly there are potential problems here. What happens to the stack? How can the handler fix-up the stack? A long-jump? But then what happens in the above case where now the DTA points to a place that will be used again for new stack space.

Open files also remain open when the Pterm is called, so these must also be cleaned up.

My point is: don't be mislead into thinking that a Pterm handler is nothing more than a simple longjump.

```

2211. MWC and pexec cooking

Newsgroup: comp.sys.atari.st
Date: 1988-03-03 22:36:02 UTC
From: jrb@dadla.TEK.COM
Message-ID: <2794@dadla.TEK.COM>
Source record: 254161

I seem to have started a couple of minor
greasefires with or without the pexec cookbook.

CASE 1:
The Mark William's C man page for pexec
is pretty misleading or wrong. It's
a user trap and I fell in it.

Pexec takes four arguments.

pexec(type, program, arguments, environment)

arguments is what args are passed to the program;

Allen Pratt has stated that "arguments"
is a string and that the first byte has
to be the size of the string! Of course
he knows what he is talking about. The MWC man page
doesn't mention this. It however does give
a C example. The example works but...

What the example does it build a string so
that the first byte in the string is a BLANK,
hence pexec will think it has a 32 byte
string. I stumbled over this when I implemented
a simple shell and used the example for dealing
with pexec. Why oh why is "cp", which is
an external program, only getting 32 bytes of
arguments I asked... Later due to Mr. Pratt
I experienced a mild form of sudden illumination.

CASE 2:
The environment argument remains unclarified. The
MWC man page gives examples basically as follows:

```
command = "\\bin\\date.prg";
args = " 200001322400"; /* note the blank :->... */
pexec(0,command,args,"PATH=\0");
```

What happens when we say "PATH=\0"?

Allen stated that if the environment arg is set to 0L,
the spawned process "will inherit the parent's environment".

I tried that and using Mark william's normal shell
runtime startoff code I ended up with the name
of the parent process as the "args". !!?? Things
worked fine with "PATH=\0". This confused

the runtime startoff code possibly?

Nonsense. Remember when Mr. T was the spokesman for the Imsai 998800 ?
That was the one with the massively perpendicular architecture. As I
recall, it was for hardcore hackers because it used no monitor.
The OS was Unith 0.3 (written in Lithp).

Is "Microsoft" a comment on Bill Gates' masculinity?

I specifically ran some tests of this feature. The tests consisted of assigning values to two variables that were identical up to N characters and printing out the results. As far as I can tell, Laser C uses flex names (i.e. no preset variable length) but, the tools they have provided only print out the first 8 characters or so. I can't figure out why they didn't make the tools work with flexnames, unless you need to give them some option to work with flexnames. I think I'll wait until the full documentation arrives before making any more comments.

< (a reasonable defense of unmoderated postings...)

This is a pretty obvious point, at least from where I'm standing...or
maybe it's just my New Yorker paranoia showing... but has it occurred
to any of those of you who are pushing for the unmoderated group that
there will be a real problem with Trojan horses getting posted?

Now, granted moderation has in the past introduced unreasonable delays
into the distribution process, but as I see it malicious postings of
dangerous programs should be a real concern of those of you who want
unmoderated postings. A moderator isn't just a bureaucratic bottleneck
for postings; he or she serves as "point-man" for the community, going on
ahead, trying out new stuff, and maybe getting a fried hard disk for all
the trouble.

I believe "ferneau" said something about all posted software being
reasonably well-tested before posting. Who do you propose to take over
this job in an unmoderated group? If we could trust everyone else out
there, an unmoderated group might work out.
But we can't.

Anyway, I've said my bit, and will shut up now.

>to malloc() instead of the typical 12-16 bytes.

The above is wrong. MWC does not allocate from the stack/heap area. If it
did, the system() call would not work. The overhead per malloc is 4 bytes.
The malloc/calloc/realloc/sbrk (and l versions of the forementioned) use the
system Malloc() call, with a granularity to avoid the Gemdos Malloc bug.

[lots of stuff omitted]
>
>*WHEW* Lots of stuff here... Again in dLibs, there is a function called
>pfindfile() which will use the PATH to find a specified file (with one of
>a list of extension, if there is no extension). It recognizes both ','
>and ';' as separators in the PATH list. There is also a popen() function
>which works like fopen(), but uses pfindfile() to locate the file. If
>applications used these functions, most of the above problems would be
>solved.
>
MWC provides the functions getenv() and path(). path() searches a selected
path (need not be PATH) for a particular file. The "popen()" function
provided by dLib is useful, but its name conflicts with the popen() unix
function. Some people may feel this is not a problem, but portability is
a major issue at MWC. Rather than clutter up the documentation and
library with functions that are a simple combination of other functions
we let the user construct his/her own.

None of the above is to disparrage the work or comments of Dale Schumacher,
who has done the ST programming community a great service, and whos
contributions are appreciated by many, including myself. I don't have
dLibs, I managed to miss it, but I find that his postings are usually
very useful.

MWC remains committed to providing a complete and robust library with
complete and accurate documentation. The documentation does lag the
library, but we have only withdrawn one standard Unix library function,

crypt, from the library (it was never documented) since we first shipped,
and with each new release, the library becomes more populated.

I am not pursuing Atari ST development at this time, and so would like to sell my Atari ST Software Development kit. The kit itself, which lists for $300.00 new, consists of 5 disks: Utilities, Compiler, Linker, Resource Construction Set, and MicroEmacs; and a BIG documentation set (about 1600 pages). I am asking $135.00 plus shipping.

I am also selling my Megamax 'C' Language Development System for the ST. Megamax, which lists for around $180.00 new, comes with two disks: System nd Utility; and bound documentation. I am asking $60.00 plus shipping.

Those interested may contact me over the net, or via USPS at:
6959 Yale Station, New Haven, CT 06520
(203)436-2696 (serious inquires only; no collect calls please)

> someone to confirm this).

The following program succeeds on my system. I'm using MWC version 2.0 and the Nov 20 1985 version of the TOS ROMs. The program stops after 10,000 repititions. When the address returned by Malloc was displayed, it was always the same.

```
#include <stdio.h>
#include <osbind.h>

main()
{
long buf;
long count = 0;

printf ("%ld bytes memory available.\n", Malloc(-1L));

while (1) {
if ((buf = Malloc(1000L)) < 0L) {
printf ("Malloc stopped giving memory after %ld calls.\n", count);
break;
}
if (++count > 10000L) {
printf ("Malloc ok after 10000 tries.\n");
break;
}
if (Mfree(buf) < 0L) {
printf ("Mfree failed after %ld tries.\n", count);
break;
}
}

}
```

2222. CT version 2, documentation.

Newsgroup: comp.sys.atari.st
Date: 1988-03-04 06:51:31 UTC
From: jafischer@lily.waterloo.edu
Message-ID: <3476@watcgl.waterloo.edu>
Source record: 254173

I'm posting my copier program, called 'ct'. Complete description is
in the documentation below; however, in brief:
- maintains timestamps from source to destination file.
- copies directory trees
- performs selective backup
- handles wildcards (i.e., can be called from the desktop or from
within a program like 'Flash').
- works on all STs (well, I don't have a Mega to test with, but if it
doesn't work on one then I'd be really surprised), in all
resolutions.
---------- Cut here ----------

Mar 4 01:18 1988 ct.doc Page 1

You may have noticed that when you copy files with the Desktop (by
dragging icons), the new files created by the copy have a timestamp equal to
the current date and time, rather than the timestamp from the source file.

For many situations, this is not a problem. However, it is often
useful to maintain this timestamp when copying. Since many command-line
copying programs (typically named 'cp' after the Unix command) for the ST are
also plagued with this problem (the ones supplied with "Gulam" and Beckemeyer's
Micro/MT C-Shell being exceptions), I wrote my own, and called it CT, for
'copy with timestamp'.

It wasn't until after I wrote CT that I discovered that Gulam and the
MT Csh had solved my problem. So why bother continuing to update and improve
CT, you ask? Mainly because of the additional capabilities that I've added
since the original version, namely:

- now copies whole directory trees with the '-r' option.
- allows selective backup of files with the '-b' option. (e.g.: you're
working on a ramdisk, and saved all your files to floppy 20 minutes
ago. Before you run your test program, you want to save all the
files have changed since you last saved them to floppy.
"ct -b * a:\" will do this.)
- can request user verification if the destination file exists
**** - accepts wildcard file specifications, so that CT may be called up
from the Desktop. (Or from the Megamax graphical shell, or from
within Flash, for instance). (** See description of wildcards,
below).
- also, if called from the Desktop, waits for a keypress before
exiting.

Now, Gulam does have a '-r' option; however it doesn't seem to copy the
actual directory structure, but only the files themselves that are contained

in the directories. With CT, if you specify
ct -r a:\{bin,lib,work} c:\
then the 3 directories themselves, as well as their contents, will end up on
c:\ (just like it works on the desktop when you drag folders).

GEMDOS BUG 'FIXED': You may also have noticed (if you work with
floppies a lot from command shells) the following problem: you are working
from a ramdisk directory, and you want to copy a file from a floppy onto the
ramdisk. You remove the floppy that is in the drive, and insert a new floppy.
Then you type, "cp a:\folder\file.nam c:\" or some such thing, and the copy
fails, with "can't open a:\folder\file.nam". If you then type "ls a:\" and
repeat the copy command, it will work. This problem is fixed in CT. GEMDOS
for some reason won't access files in subdirectories when a disk is changed,
until it has a look at the root directory on the new floppy. I basically
force it to do this if I can't open the file.

CT is also fairly robust:
- when expanding wildcards, CT can handle up to 2000 files in total.
When copying directories, CT can handle up to 2000 files rooted in
one directory. This limit may easily be increased by modifying
a #define in the source.
- will allocate a very large buffer (I have it #define'd to try for
500K). This really helps when copying from a: to b: with one
drive (although be warned: there are still a couple of swaps per

file).
- if you are working under the MT Csh and you want to use CT in the
background, then you can specify the '-m' option, to restrict CT
from hogging all available memory.
- when performing a recursive directory copy, CT checks for stack
overflow.
- if a file is not successfully copied, CT deletes the destination
file.

Wildcards:
==========
* - match with any string of characters.
? - match with any single character.
[] - match any one character within the brackets. Ranges of characters
may be specified as follows: [a-zA-z] meaning any lower or upper
case alphabetic character.
{} - match any of the specified groups of characters, e.g.
{word1,word2,word3} will match with 'word1', 'word2', and 'word3'.

Some examples:
a:\{bin,lib,include}*.c
- matches with all '.c' files in a:\bin, a:\lib, and
a:\include
*
- matches with all filenames, with or without extensions.

c:\work*.[ch]
- matches with all '.c' and '.h' files in c:\work
[d-q]*
- matches with all files beginning with the letters 'd'
through 'q'.

Interesting tidbits:
====================
(more than you care to know, probably, but hey, this is my moment on the soapbox so let me enjoy it...)

- In testing CT, I created a directory tree containing around 2,000 files of zero length, strewn among several directories. CT handles this fine, thank you, but GEMDOS just died disgracefully when I tried to delete these folders. Not even a warm boot would resuscitate the ramdisk!

- An easy (but not flawless) way to determine if a program has been called from the Desktop is simply to check if argv[0] is an empty string. Most ST shells (msh, Gulam, MT Csh) will set argv[0] equal to the program name, i.e., "ct". However, if a user is, er, 'using' a command shell that doesn't follow this standard practice, CT will assume that it is being called from the desktop, and will wait for a keypress before exiting.

- If you go through the source code, you can't miss the inelegant method I use to allocate as large a buffer as possible. It's very evident that I'm not using the standard Malloc(-1L) method. Why? Apparently (from all I could tell) you simply cannot mix Malloc() and MWC's malloc() routines in the same program. As soon as Malloc() is called, malloc() will refuse to allocate any memory. Since

I doubt that Malloc() will perform 2000 allocations (I think that the fixed limit is well below that), I'm forced to use malloc().

- Cconws(NULL) seems to print one backquote ("`").

- When run from the desktop as a .ttp program, the first tab printed doesn't seem to behave itself. Just try running ct.ttp with no params, and you'll see what I mean. (Although I have some very old ROMS, so it your mileage may vary).

- Fread() doesn't seem to return an error code. Even if I get the "Data on the disk in drive A may be damaged..." alert box, I don't get a negative return code from Fread().

>have all been dismal financial failures that haven't returned anything,
>and certainly not something similar to what the author would have made
>as a programmer or consultant in regular employment.

May I point something out here...discounting the throw-away Shareware programs (i.e. The ones you download and never use again which are by default labelled "send money") the risks in marketing legitimite shareware seem to fare equally with any other individual entreprenurial venture. The failure rate in small buisnesses, for example, is by SBA statistics 90%. Given that a shareware author is basically running a small business, its not surprising that the failure rate for such ventures is so high.

But then again, I wouldn't sell any of MY programs shareware...but realistically I don't believe that it is as bad as most people make it out, Shareware really is a viable alternative for those who don't have the capital to handle distribution properly.

Posting for a friend:

My friend has lots of DRAM for sale.

Couple of hundred of HM50256-15 DRAMS
These are Hitachi 256K x 1 150 ns CAS before RAS Drams
Standard for ATs and Turbo XTs with 640k on board
Also several dozen TMS 4256-15 - Texas Instruments 256Kx1 150ns
He wants $6 a piece in multiples of 9

Several hundred of xx64-15 DRAMS
64K x 1 150ns standard Drams
These will go for $2.50 a piece in multiples of 9

Reply to me if interested

>almost all problems. The problem is definitely not ATARINET!
Sure isn't, I have got lots of programs from ATARINET - thanks to UACE.
I do however have to fix all files before I uudecode. The problem is that
our local VM system uses the Danish version of the EBCDIC character set,
and the conversion from US EBCDIC is not done very well. I sugest that
you try to download one of the newer files encoded with the newest version
of uuencode. These files contain a table of the characters used. If you are
in luck you may be able to deduce from that table what characters to
change. It would defenitly be a help i all files was decod with the
newest decoder.

2230. UniTerm 2.1a wishlist/Broken ST problem...

Newsgroup: comp.sys.atari.st
Date: 1988-03-04 09:59:56 UTC
From: sqrkl@csvax.liv.ac.uk
Message-ID: <460@csvax.liv.ac.uk>
Source record: 254180

Wishlist for the next release of UniTerm (2.1a ??) :

1) Support for 'invisible cursor' (ESC [1 v I think...).

2) Double width, single height text on colour monitors.

3) Faster Tektronix mode.

4) A one-key NO SCROLL key (none of this ALT-Z stuff) - I currently use
INSERT to go in and out of the SLE...this acts as a useful NO SCROLL key.

5) Why does an alert dialog appear if you disable the SLE and then (accident-
ally or deliberately) press the INSERT key ? This rather makes the 'dis-
abling' aspect a bit useless...!

6) Retain the screen display when switching from or to 132 column mode, rather
than clearing the screen and homing the cursor.

7) Follow this convention for mouse control :
If there is keyboard input or serial line activity, leave the mouse
switched off UNLESS the mouse is moved (switch it back on again in that
case). Use either the standard mouse arrow or an outlined char cell box
for the mouse because these are easier to use than the I-bar.
If the mouse button is clicked whilst the mouse is on, then the cursor
should move to the character cell nearest to the mouse pointer. BUT....
listen to the echo from the host after each cursor arrow code is sent -
then the cursor can be 'stopped' if it exceeds the selected position
(as is the case if there is tabs between the original cursor position and
the destination position selected by the mouse).
PLEASE remove this silly 2-click convention for cursor position selection
by the mouse - it is highly annoying.

P.S. MY ATARI DOESN'T RECOGNISE ESCAPE (AND NEVER HAS !) to refresh a disk
window after a disk swap. Also, the Procopy disk copier is convinced
that the source disks I put in are write-enabled when they are clearly
write-protected. By the way, I'm using a 1040STF that is about two years
old, but I'm not sure which drive manufacturer produced my internal drive.

> such crap, go write it on a bathroom wall or tattoo it on your
> ass!!! And while you're at it, try to come up with some valid
> arguments!

OK, you asked for it ...

1) The Atari ST's OS has been ported from an IBM PC and has several features removed (no fonts for example) and has had several (hundred ?) bugs introduced (40-folder bug, can't rename a folder, can't rename a disk...).

2) The ST has the same sound chip as a Sinclair Spectrum Plus 2 - a prime example of Atari ST cost-cutting.

3) 99% of all available software is either a very poor imitation of Macintosh software (First Word Plus, Publishing Partner, Fleet Street Editor etc.) or just a poorly-written arcade game...

4) Virtually all the compilers I've seen (and I've seen plenty of them !) for the ST have been quite disgraceful. They either have numerous bugs, have a user-hostile interface (such as a cryptic command line) or are extremely slow. This just shows that ST software companies are in the market to make a quick buck off people foolish enough to buy an ST in the first place.

5) The official ST hard disk is appalling. A friend of mine was so disgruntled that he ripped out the Atari mechanism and replaced it with a faster hard disk mechanism.

6) As mentioned in comp.sys.atari.st, Atari have been caught red-handed shipping STs with faulty disk drives that don't sense the write-protect notch on a disk correctly...typical of such a cost-cutting company (price without the power - or safe disk drives !)

> Calling the ST a "hunk of dross" is uncalled for. The Amiga

> Vax and IBM mainframe machines are all "dross" because a better
> computer exists. Grow up, and take a course or two in logic
> before you waste our time with childish bullshit.

I never said that the Amiga/VAX/Mac etc. were the BEST computers in the world - just that they're BETTER than the ST !! My philosophy is that if the machine

is fast, has a good OS and a good (high level) language then it is GOOD. If it doesn't have these attributes then it is BAD (aka DROSS).
From your rabid defensive posting, I can only assume that you are an Atari victim..oops, sorry...owner. This is why I've pointed out what a mistake Atari owners make when they part hard-earned money for what, in effect, is a very large door wedge.

2232. Atari 6.5 Icon memory problem.

Newsgroup: comp.sys.atari.st
Date: 1988-03-04 13:47:22 UTC
From: NETWORK@FRSAC11.BITNET
Message-ID: <8803041517.AA19085@ucbvax.Berkeley.EDU>
Source record: 254182

About Icon 6.5 for the Atari ST:

The release (e) as distributed, was a little tight in heap memory
available, aborting for some programs with a message complaining
about not enough space. (e.g. #309 or #310)

The MCC library for the C compiler is weird about memory management.
To overcome this, at execution time, you can change the heap size by:
iconx %300000 program-name
Where %300000 is an example of the heap memory size you request.

By default this request is 200000, enough to run all the Icon test suite
programs, but not enough for some other.
On a 1040ST, without shell, you can try up to aroud %700000.
This MCC "feature" *cant* be used from Icont, with the -x option.
(The % arg is not passed to iconx, but used by icont, that does not
need it.)

A modified version (f) with a default of 260000 is released,
and sent to:

userczak@ualtamts (bitnet)
listserv@canada01 (the useful prog-a16 server, on bitnet)

> being too expensive, eaven at bronze medal prices) for Atari to ever do.
>
I don't believe that it would be anywhere as expensive as an actor or top professional sports personality. I think this idea has a lot of merit and I hope Atari considers it seriously.

> This is aside from the misbegotten perception that the computing world is
> too lily white in the eyes of the ad executives to accept a person of color
> as a spokes person (ever wonder why there are no endorsements for the top
> black tennis players?).

Someone must have forgotten to tell the ad executives that Bill Cosby is black (:-)). Actually, I also see Arthur Ash is an ad for an aspirin product even today. I think the main problem with black tennis players is that there isn't anyone with name recognition that the majority of the public will instantly say 'oh, that's (substitute any name you can think of here)'.

From: MARKS@HDETUD53.BITNET
Message-ID: <8803042134.AA23120@ucbvax.Berkeley.EDU>
Source record: 254184

Distribution-File:
info-atari16@score.stanford.edu

Before I have my American 1040ST sent over here to Holland, I would feel much more confident if I could get some hard information from someone who's done the same thing. Not necessarily to Holland--I guess that all European power is the same 220V, 50 Hz. Have people tried this, and has it been successful? I was told that I only have to convert the voltage; the frequency is supposed to be OK, since I have the monochrome monitor. Any confirmations?

I was told that adaptor/transformers were easy to get in the US. Unfortunately, I assumed they would also be easy to find here. I can't find anyone that has one. Can anyone give me a recommendation on this? Should I just buy a 2:1 transformer and solder something together? Is there any way this could get me in trouble?

Please respond to MARKS@HDETUD53 (BITNET).

Appreciatively,

Roger Marks

2235. samplers for atari

The phrase 'THE AUTHOR OF AMIGADOS' is perhaps a bit strong. However, in essence this is true.

On the other hand, (and, much as I love my ST, and much as I worry about starting another round of flame wars), AmigaDOS is OK, really. (Personally, I prefer GEM/TOS, but that's a totally subjective judgement.)

And, to the people who've been offering to explain multi-tasking to me, GO AWAY! I've been using it since probably well before most of you had cut your second pair of teeth. I'm *still* not convinced it's a good idea in an environment where the tasks are not protected from each other.

Thanks.

2238. Atari ST Developers Kit -- SOLD

2239. problem with Magic Sac + Uniterm ver. 2.0a 20

Newsgroup: comp.sys.atari.st
Date: 1988-03-04 20:15:00 UTC
From: SYSTEM@UVPHYS.BITNET
Message-ID: <8803050005.AA25381@ucbvax.Berkeley.EDU>
Source record: 254190

One of our users reported the following problem when he tried to run
Uniterm ver 2.0a 20 with the Magic Sac connected to his ST:

Configuration: 1040 ST with 20MB SH204 hard drive, Magic Sac+Translator box
the Hard disk has 3 ST and 2 Mac partitions (created with Magic Sac).
When he tried to use Uniterm 2.0a 20 (from floppy) when Uniterm came up it
destroyed the Mac partitions on the hard disk (ST partitions ok).
He recreated his Mac partitions but every time he run Uniterm the partitions
were destroyed.
He then switched back to Uniterm 1.8a20 and everything worked fine.

Does anyone know (Simom??) why Uniterm 2.0a 20 cannot coexist with the
above hardware set up?

> in the Unix minicomputer world.

The database slated to run under Idris on the ST was Oracle. I hope to
see it happen, unfortunately Atari has to wake up and start supporting
the developers out there. Idris is a multi-user multi-tasking Unix like
operating system. I really enjoy using it, I work on various Unix systems
at work, and feel right at home working with it. I have been porting some
public domain utilities and games for Unix machines, and find that there
is little or no work to get them running under Idris. The C compiler and
utilities are very nice. My only complaint is that it needs a "csh".
I miss history, and cd ~foo etc. (any one have public domain sources for
a csh like shell).

P.S. I have seen and touched X windows (X10) on the ST!! --stayed tuned--

2241. MORE on the 16Mhz board

Newsgroup: comp.sys.atari.st
Date: 1988-03-04 22:35:26 UTC
From: keithr@vice.TEK.COM
Message-ID: <2331@vice.TEK.COM>
Source record: 254192

Here is some more info on the 16Mhz board for the ST.
It is a board the that mounts inside the ST. The
installation is said to be more difficult than a memory
upgrade. The replace the cpu with a 68016(?) and
place a switch on the back of the ST to allow you to
switch from 8Mhz to 16Mhz. They are expecting their new
(lastest) board next week. After they do some more testing
they expect to go into production in about a month. They
hope to keep it in the $200 range not including installation.
They're looking into setting up dealers for installing the
board, but are looking into other options as well.

I asked if there is a problem with 150ns memory chips he said
no, but going to 120ns chips would increase the speed, then
only slightly.

PC Ditto is running on it. They haven't found any software
that doesn't run, but who knows how much they've tried.

The person I talked to was named Kevin. He was very helpfully
in answering any questions I had. He said if people send
in a self-stamped addressed envelope they would send back
literature on this and other products, hardware upgrades
such as blitter upgrades, for the ST.

The address is:

MEGABYTE Computers
109 W Bay Area Blvd.
Webster, TX 77593
713-338-2231

(I am no way connected with MC, I don't own any of their stock,
and I am not married to any of their sisters.)

2243. Upgrade

Newsgroup: comp.sys.atari.st
Date: 1988-03-05 00:03:01 UTC
From: BUJOLDJ@UDEM.BITNET
Message-ID: <ID9060.D880304.T200301.BUJOLDJ@UDEM>
Source record: 254194

Part 1.
Creator: Jean BUJOLD / CUM/ET

TO: N / RESEAU &
(info-atari16@score.stanford.edu)

Part 2.

I'm new at this so I hope it gets to the atari16 digest.

I own an Atari 520 ST with single drive. I was wondering how much it cost to upgrade it to a 1040 ST and if it is possible to do it by myself. Also I have requested from my local listserv a few atari programs that it has in memory. It send them to me without a problem. However I transfer them to my atari but from there I can't de-arc them. I'm using a arcx program I got with the Start magazine, but it tells me that there is a bad header. How do you get it to work?? Am I using the correct de-arc program? And if not where can I get the right one.

In simple terms, What I'm trying to say is HEEEEELLLLLLPPPPP!

2244. freeware for marching band

Newsgroup: comp.sys.atari.st
Date: 1988-03-05 00:48:45 UTC
From: S071768@UMRVMA.BITNET
Message-ID: <8803050720.AA01970@ucbvax.Berkeley.EDU>
Source record: 254195

I have developed a program that i have used for marching band show design.
It runs only on a monochrome st. If their is interest I could post it
to listserv at canada01 or to the atarinet in houston since I am on bitnet.

A little bit about the program:

there are several marching band programs commercially available but none for
the atari. I believe that this program is the easiest of all marching band
programs to use. you can get results quickly. The biggest difference between
it and other programs is that with this one you can design your show on the
computer, not just transfer it to the computer after designing it on paper.
it handles curvilinear shapes using cubic splines and it allows grouping of
shapes into objects. It has a perspective view from any angle but does not
have animation.

I have 10 to 15 pages of documentation describing the features and explaining
their use.

If anyone out there has a need for this program let me know.

Thanks.

Kevin Schneider -- University of missouri - Rolla

MadMac 1.0 is capable of generating MWC object files just fine, thank you. (The most recent version I'm aware of is 1.04 -- I just called it "1.0" and more or less done when I left Atari).

The MWC assembler is a horror, and their linker is slow. If you're an assembly-language-only kind of person, MadMac and ALN in the MWC enviroment make a pretty good team. I used Alcyon C and ALN, which wasn't too bad.

The printer variables you discovered in the "atari.s" equates file that's included with MadMac are indeed reality.

Does anyone know if an IBM PC compatible version of GULAM is available
It would be really nice to have a consistant environment at home and at
work, and I really like GULAM.

Barring that, does anyone know where I might be able to get my hands
on the C source code for GULAM and I'll port it myself???

Thanx

2247. Is anyone porting the MM File Selector to MWC?

Newsgroup: comp.sys.atari.st
Date: 1988-03-05 08:43:00 UTC
From: lansd@godzilla.ele.toronto.edu
Message-ID: <1988Mar5.034301.22732@jarvis.csri.toronto.edu>
Source record: 254197

Is anyone trying to port the recently posted file selector
code written in Megamax to Mark Williams C? I tried in vain back in
September/October; I got it to finally compile but it never interpreted
mouse events properly - it seemed very tricky to debug. Anyone else
want to give it a try? Its a great file selector, and the author has
given permission to the programming community to do what it wants with
it!

>together a prototype 68000 machine in six months is an amazing task.

Yes, it would have been amazing, had it actually happened. When Tramiel took over Atari, though, there were already people working on a 68000 machine, and had been for some time. Those people were, essentially, the only ones that Tramiel kept when he purged the company. While the final ST design might have had significant Tramiel influence (it looks it - it's cheap enough), it's pretty clear that the groundwork had been laid before he ever came on the scene.

>> using either a CGA or EGA card? Was it successful? Can it be done?
>> If so, where can I get the cables?

You can make it work with a CGA card if you build a TTL - Analog converter,
which isn't too hard. You cannot make it work with ANY other IBM video
card, as the horizontal and vertical sync rates for those video cards
are way off from the standard NTSC values the Atari color monitor uses.

From: Harold_Hank_Hagquist@cup.portal.com
Message-ID: <3675@cup.portal.com>
Source record: 253955

You can use 256K chips to go up to 1Meg of total memory. If you want to go any higher you need to go to 1Meg chips. This is because to ST can only access 4 banks of chips. If you want an up grade board, I can get you one. To upgrade to 1Meg (using 256K chips) the board is $250.00. If you want to go to a higher upgrade (2 to 4 Meg.) the bare board is $200.00 plus each chip is $20.00. This means if you want to get the board with 2Meg of memory it will cost you $520.00. This is the price at this time as chip prices are very shakey. The ST power supply will handle the extra chips. The above prices are all US dollar You would also need to pay shipping prices above this.

2257. Re: problem with Magic Sac + Uniterm ver. 2.0a 20

Newsgroup: comp.sys.atari.st
Date: 1988-03-05 19:53:53 UTC
From: dsmall@well.UUCP
Message-ID: <5376@well.UUCP>
Source record: 253957

In the base note, Nik Zapantis asks if there's any known incompatability between Uniterm and the hard disk under Magic Sac.
I don't believe there is; without further details, it's hard to know for certain. The only bugs I know of that have been reported in the hard disk implementation are that a) Finder/Systems above 5.4/3.2 should not be used (possible disk damage report), and b) filenames longer than 21 characters cause problems under an HFS hard disk, and can damage the directory structure.
In short, I would think at first glance the problem isn't Uniterm, but rather a long filename or too recent a Finder/System. However, murphy's law always applies, especially at dP.
Thanks, Dave Small / dP etc / My opinions are my opinions.

Does this mean that the magazine publishers think people buy their publications SOLELY for the type-in programs? I always bought an issue of (fill in your favorite magazine here) for the articles/tutorials in it. Type-in games and programs are merely icing on the cake.

Besides, has any magazine ever persecuted anyone for uploading a type-in program to a BBS, or for distributing copies of a type-in program? Seems like a really minor point to me...

This isn't entirely accurate. Publication without a notice that the author claims a copyright in the work releases the work into the public domain SO LONG AS THE PUBLICATION WAS DONE WITH THE COPYRIGHT HOLDER'S CONSENT. I'm sure that's what you meant but there seems to be a lot of confusion about the copyright law and I wouldn't want anyone to think removal of a work's copyright notice followed by publication would put it in the public domain.

2261. Micro RTX Description (long)

Newsgroup: comp.sys.atari.st
Date: 1988-03-06 00:27:33 UTC
From: david@bdt.UUCP
Message-ID: <169@bdt.UUCP>
Source record: 253968

A BRIEF DESCRIPTION OF MICRO RTX

In response to all the requests for information about Micro RTX,
I began working on a document for eventual posting. Before I
finished it, I realized that it was rapidly becoming a very large
book. I therefore have prepared this summary.

There is a lot to RTX and there is a lot of general Atari ST knowledge
and multitasking operating system knowledge that has to be aquiried
before one can even begin to learn RTX in detail.

This document describes only briefly the Atari ST system architecture
and it barely scratches the surface of RTX and multitasking on the ST.
Unfortunately, it just isn't possible to fully describe it in a net
posting.

INTRODUCTION

RTX is a Real-Time Executive. RTX is accessed with system calls,
like the standard TOS/GEMDOS/BIOS services. It is not a command shell
and it doesn't have any "commands" or user interface intrinsic to the
kernel. It is a system call handler.

Atari ST programs make use of the TOS operating system via "system calls".
The whole TOS operating system has GEM calls (several different types),
GEMDOS calls, BIOS calls, XBIOS calls, and LINE-A (graphics) calls.

After Micro RTX is installed, it intercepts and interprets the GEMDOS,
BIOS, and XBIOS calls for all programs. Micro RTX also implements
several RTX-only calls and GEMDOS extensions.

PROGRAMMING OVERVIEW

Programs can call TOS directly. In C, this is done with the "osbind.h"
macros like Fopen, Dgetdrv, and Rwabs. These macros actually produce code
that cause a software interrupt, or trap, which jumps into the ROM code.
The application can also use library routines provided by the compiler
manufacturer (e.g. fopen, or printf). These library routines then perform
the TOS system calls on behalf of the calling program. For example, the
fopen C library routine will eventually use the Fopen system call to open
a file.

It must be understood that there are important differences between
library routines and system calls. The code that implements a library
routine is contained within the application program (it is linked in).
There is a separate copy of the printf handler linked into every C
program that uses printf. These library routines may also "cook" the

programmer's input arguments (e.g. fopen might treat certain file names as a special case), before they call the actual operating system. It depends on the compiler manufacture's particular idea of "correct" implementation.

In contrast, the code that implements system calls is normally in the TOS ROMs. There is only one Fopen handler; all programs use the same one.

When RTX loads, it replaces the system call handlers with RTX RAM resident versions. Therefore, there are no changes to the application. The only difference is a new system call handler. This is one of the really nice things about RTX. While RTX does add new system calls, it is optional whether a program wants to use them or not.

Programs using only standard TOS calls operate as usual. Programs that require special functions that are only available with the RTX system calls, (e.g. interprocess comminucation, or multi-tasking) can implement only the RTX calls that are needed.

This means that there are far fewer new operating system calls to learn. Only the extended features that were not built into TOS need to be learned; all the features you already know work substantially the same, with only perhaps some new options added.

It also means that standard program development practices can be used to develop RTX applications. The applications can even be developed with compile-time or run-time options, to run with or without RTX installed. Any language capable of producing system calls can be used to develop RTX programs: C, Pascal, Modula, or Assembler.

In C, RTX calls look like regular function calls. In assembler, they are trap instructions (just like the GEMDOS, BIOS, and XBIOS calls).

OVERVIEW OF RTX SYSTEM CALLS

RTX implements two separate types of system calls:

- stand-alone Real-Time services
- TOS compatible services and TOS extensions

Both types of system calls may be used in the same application.

The RTX Real-Time kernel provides Real-Time multitasking services similar to many popular Real-Time systems, such as VRTX, pSOS, etc. These commercial systems sell for thousands of dollars. Micro RTX compares very well with these systems even at its low price. There's no way to give a complete description of what a real-time operating system is, and what one is used for here. For those that know what it is, little more needs to be said; for those that don't know what it is, don't worry about it. For those interested, we have lot's of nice color brochures that describe the real-time properties of Micro RTX for commercial Real-time applications that we'd be happy to send you.

RTX is designed to be easy to use. The calls are simple and general. The calling conventions are consistent and the chance for errors and confusion has been reduced.

The basic philosophy is that a few very general building blocks can be put together lot's of different ways to accomplish lot's of different goals.

This has the drawback that the application developer must have the vision to know how to put the pieces together effectively. When a developer needs function X, and RTX has no X, the developer needs to be able to build X from what RTX does have. It's analogous to UNIX users who know what you can do with pipes and those that don't (so somebody has to write them a shell script that does exactly what they want with no pipes).

Configuration relies on a small number of passive declarations; RTX is mostly self-configuring.

THE PROCESS

A process is an entity in the system. The terms process and program are NOT the same thing. A program is a file that contains code and data that can be loaded into memory and executed. A process is a running entity, or "being" in the system. The code loaded in from one program can become a process when it's executed; a single program may even become several processes when it executes.

In RTX, a process is the atomic unit of CPU execution. While several processes may be "running" in the system, the CPU can only execute one process at any one instant of time. The processes appear to execute at the same time becuase of process switching. A process switch can occur for several reasons. Each process has a state associated with it. The basic states are running, sleeping, and ready-to-run.

With RTX, the running state means the CPU is executing the process. There is only one running process in the system. A sleeping process is one that is waiting for something other than the CPU (e.g a message, or event). A sleeping process consumes no CPU resources until it "wakes up". A ready-to-run process is one that is waiting its turn to use the CPU (it has work to and is ready to become the running process). There may be any number of sleeping and ready-to-run processes.

Each process has several types of memory associated with it. Each type is called a segment. All RTX processes must have all their memory segments resident at all times. A process needs a code (or text) segment and a stack segment. A process may also have a (static) data segment and a (dynamic) heap segment. These segments need not be contiguous.

Any location in memory containing executable 68000 CPU instructions can become an RTX process' text segment. Each process has a parent. A process' parent is the process that created (or spawned) the child.

SCHEDULING

RTX uses two types of CPU scheduling: priority pre-emtive and time-slice.

Each process has a priority associated with it. The RTX kernel uses
a very simple scheduling algroithm. It simply selects the process with
the highest priority from those in the running or ready-to-run states.

When more than one process occupies the same priority level, time-slicing
is used to split up CPU time between the processes. Each process has
a quantum (length of time) associated with it. When this quantum is
used up, RTX schedules the next process. This repeats as long as
several processes are at same priority (and that they are the highest
priority processes that are ready-to-run). This is also sometimes
called "round-robin" scheduling.

PROCESS CREATION

Once a process' memory segments are loaded into memory (at least
the code segment), a new process may be created. Process creation
simply is the way a process is made known to RTX. RTX creates
a stack segment for the process, and places it on the ready-to-run
list. The caller (the process creating the new process) provides
the priority, time-slice, load address, input arguments, and stack-size.
The priority and time-slice quantum may be altered at run-time.

A pid in RTX is actually the 32-bit address of the proces control
block (an internal RTX data structure) for the process.

The Pexec GEMDOS call also performs a process creation indirectly.
A direct call to the RTX p_create service will spawn and run a loaded
process (i.e. it runs a subroutine as a concurrent process). A call
to Pexec loads a GEMDOS formatted executable file, and spawns it as
an RTX process. RTX also provides a Pexec option that allows the caller
to continue processing while the child runs (like fork/exec).

PROCESS CONTROL

The RTX process control system cals are:

p_create - create and execute a new process
p_delete - delete (kill) a process
p_priority - get/set process priority
p_slice - get/set time-slice quantum
p_suspend - suspend (stop) a process
p_resume - resume (re-start) a process
p_lookup - convert process name to a PID
p_info - get the state of a process

In RTX, priorities range from 0 to 255; 255 is used for "real-time"
processes and 0 is reserved for the idle deamon. A process running
at priority 255 never gets time-sliced and will never lose the CPU
until it voluntarilly blocks (waits for something) or lowers its
priority.

INTERPROCESS COMMUNICATION - THE MESSAGE QUEUE

Processes in RTX can communicate by sending messages. The RTX message queue is a many-to-many queue, sort of a named mailbox. The idea is like UNIX creat/open/read/write/close. Each message queue has a name and QID. If a process knows the name of the queue, it can determine the QID (like UNIX open). Messages are 4 long-words (16 bytes) fixed size. The first long word (4 bytes) is reserved for RTX. The remaining 3 long-words (12 bytes) are completely user dependent. The messages may contain data, or pointers to data located elsewhere. Any process may send (write) or request (read) a message from any queue for which it has a QID (like a handle to a file).

Each message queue may be set up as a simple FIFO where waiting processes are queued in the order that they request messages, or it can be set up such that processes are queued in priority order. With a FIFO queue, messages are received (read) in the order that they were sent. With a priority queue, the process with the highest priority that is waiting for a message will receive one first.

RTX message queues can be used for many differnt kinds of interprocess communication/synchronization facilities, including simple FIFO non-interlocked (simple one-way channel), fully inter-locked (using two queues), and semaphores.

An example of many-to-many usage might be a print spool system where several processes make print requests and several printers are available. One incarnation of a print-spool handler exists for each printer (one print process per printer). There is one RTX message queue which is used for print requests. Each print-spool process requests a message from the print request queue. A process wishing to print something sends a message to the print request queue. The first print-spool process that requested a message receives the print request and starts printing the job. If another process makes a print request, the next print-spool process will print it, until all the printers are busy and there are no more print-spool processes waiting for a message, in which case further print requests will be queued on the message queue and printed by the next available print process when it requests a message from the print queue again.

The RTX message queue services are:

q_create - create a message queue
q_delete - delete (close/remove) a message queue
q_send - send (write) a message
q_req - request (read) a message (wait or no-wait)
q_jam - jam a message at the head of the queue
q_lookup - convert queue name to QID (open)
q_info - get the status of a message queue

A maximum wait interval (timeout) option may be specified when requesting messages. In this case the caller is awaken when either a message is available or the wait time has expired.

The q_send and q_jam system calls may be made from interrupt service (ISP) handlers. A special RTX trap is used upon exit from the ISP to force a pre-emtive reschedule (if necessary).

RTX EVENTS

UNIX programmers beware: RTX events are not anything like UNIX signals.

The RTX event system is a many-to-one synchronization facility. Each process has associated with it a set of seven user events and seven system (reserved) events. A process can signal a single or a group of events to another process with a single call and it can wait for the occurance of one or more of its own events.

What event is used for what is completely up to the application developer. RTX places no restrictions on the use of the seven user events. The primary limitation of events is that, unlike messages, events are not queued. Where overrun is impossible or can be handled, the event system does offer the advantage of specifying multiple events.

The event system calls are:

e_signal - signal a group of events
e_wait - wait for one or more events

A process may wait for any of a group of events, in which case it will be awakened when any of the specified events is signaled, or it can wait for all events, in which case it will not be awakened until all the events are signaled. As with messages, a maximum wait interval may be specified to handle timeout situations.

The e_signal system call may be used in ISP routines for real-time pre-emptive applications.

RTX MEMORY MANAGEMENT

RTX uses a first-fit memory allocation algorithm. Memory segments are allocated from system heaps. The RTX kernel splits the first section large enough to meet a users request, returning any remainder back to the free pool. When a segment is released back to RTX, it is merged with its neighboring segments, if one or both of these segments are free.

The RTX memory management calls are:

m_alloc - allocate a memory segment
m_free - free a segment
m_assign - transfer a segment to another process

The GEMDOS Malloc system call uses the RTX m_alloc system call to allocate memory when RTX is installed (this solves some TOS memory management problems).

REAL-TIME PAUSING

RTX provides a call that allows a process to schedule itself at a regular interval, or sleep for a duration of time:

p_pause - pause (sleep) for a specified time interval

The time interval is specified in miliseconds.

TOS GEMDOS AND BIOS EXTENSIONS

As stated elsewhere, the Micro RTX kernel processes all GEMDOS and BIOS system calls. All Device and File I/O system calls are handled by the RTX kernel.

In addition to providing compatibility, RTX also implements several extended GEMDOS and BIOS services. The GEMDOS system calls are:

Pexec - supports "execute concurrently" mode
Popen - Pipes using GEMDOS file handles
Ftype - Determine if handle is file/pipe/device
Flock - File record locking
Fcntrl - GEMDOS-level character device control
Psettpa - control the startup TPA (stack) size
Mquota - limit the Malloc(-1) maximum

The Popen service combined with GEMDOS I/O redirection allows any TOS program using GEMDOS STDIN/STDOUT to be used in pipelines (i.e. the programs do not need to be recompiled to work with pipes).

The Flock call provides file locking for multiuser file access. Any region of a file may be locked (even beyond the end-of-file). When another process attempts to read or write the locked region, the operation will fail, in which case the application may take appropriate actions (i.e. pause and try again). For application developers that wish to implement file record locking in their applications, but do not wish to purchase the Micro RTX Developer's Kit, contact Beckemeyer Development at the address below for details.

The Fcntrl function alters the behavior of character (tty) devices for GEMDOS I/O operations. In the normal case, I/O to terminal devices is "cooked". Using Fcntrl, a program can force NOECHO and/or RAWIO modes.

The BIOS-level RTX extensions are:

d_install - install a custom device driver
d_cntrl - BIOS-level device control

The installable device driver mechanism allows the developer to install or replace BIOS devices. The devices are accessed with the Bconxxx BIOS calls, using the device number field. The standard BIOS devices are:

0 - PRN - Printer
1 - AUX - RS-232 port
2 - CON - System console (screen/keyboard)
3 - MIDI - Midi port

4 - KBD - Intelligent keyboard

From GEMDOS these devices may be opened by name (the standard names work with or without RTX installed). For example:

```
fd = Fopen("aux:", 2);
```

Will return a handle that will read/write charcters using the RS-232 port. Under RTX, devices may be installed with a BIOS number and GEMDOS name. The device may then be accessed just like any other device in the system. For example, say we have installed a driver for our custom high-speed I/O board as BIOS device 10, and GEMDOS name "fio", then:

```
Bconout(10, c);
```

would send a character to the device, and

```
fd = Fopen("fio:", 2);
```

opens the device for read/write, and returns a GEMDOS handle in fd that can be used in any GEMDOS I/O call that uses handles:

```
Fread(fd, count, buf);
```

Reads 'count' bytes (normally using a line editing mechanism but this can be changed by using the Fcntrl call). Likewise:

```
Fwrite(fd, count, buf);
```

writes to the port. The following calls would redirect the standard I/O handles to the special device and then execute a program:

```
Fforce(0, fd);
Fforce(1, fd);
Pexec(0, "shell.prg", tail, env);
```

This would cause the program "shell.prg" to send it's output to the special device and read its input from the special device without recompiling.

A device driver may itself use BIOS calls; so one driver can access another driver to as many levels as needed.

As can be seen, the installable device driver facility is one of the most powerful and flexible features of Micro RTX.

SUMMARY

Micro RTX is the result of more than two years of reasearch and development. This is not a fly-by-night "hack" to standard TOS. It isn't a simple scheduler on top of TOS like some of the systems I have seen are.

When looking at multitasking kernels that work with TOS programs, remember there's more to it than just adding a time-slicer. The regular GEMDOS/BIOS handlers are NOT reentrant. The GEMDOS loader doesn't know how to deal with more than one process family (tree). It holds the running PID in a static variable. The multitasking kernel must

perform all program loading, exec'ing, and memory allocation, otherwise
TOS will get very confused, usually resulting in crashes and/or trashed
files.

mcvax!ukc!mupsy!liv-cs!sqrkl, Richard K. Lloyd writes >Wishlist for
the next release of UniTerm (2.1a ??) : Please write to me personally
about things like this, I can't promise an answer (I get a hell of a
lot of mail), but I will read it (not that I would normally answer a
letter with such an agressive undertone).

>2) Double width, single height text on colour monitors.

If you want to design 6 fonts, three in a 4x4 cell, and the other half
in a 4*2.5 (:-)) cell, your welcome. Seriously, designing fonts is a
LOT of work and adding more fonts means the program gets larger
(besides I don't have a color monitor to try any color stuff out (not
that it would help, my ST is so old that it's got a GLUE chip that
won't drive a color set properly (not even the joystick port works)).

>3) Faster Tektronix mode.

The vector
drawing is fast enough for 9600 baud, at least I've never had any
trouble with it. I relize the text mode is slow, but somewhere I have
to draw the line, or else I'll end up reimplenting the whole OS.

>4) A one-key NO SCROLL key (none of this ALT-Z stuff) - I currently use
> INSERT to go in and out of the SLE...this acts as a useful NO SCROLL
> key.

If you hold down the <Alternate> key, you've essentially got a one key
NO SCROLL key, anyway in the more recent versions you can actually put
the no-scroll function on any of the programmable keys.

>5) Why does an alert dialog appear if you disable the SLE and then (accident-
> ally or deliberately) press the INSERT key ? This rather makes the 'dis-
> abling' aspect a bit useless...!

No it doesn't, you obviously don't understand why it can be disabled...

>6) Retain the screen display when switching from or to 132 column mode,
> rather than clearing the screen and homing the cursor.

Wrong! No VT1XX, VT2XX or VT3XX compatible terminal works this way,
all clear the screen and home the cursor. The command set of D*C
compatible terminals has no provision for dealing with mixed length
lines (I can think of all kind of perversions you would have to deal
with, if you want to have a terminal with this feature).

>7) Follow this convention for mouse control :
> If there is keyboard input or serial line activity, leave the mouse
> switched off UNLESS the mouse is moved (switch it back on again in that

> case). Use either the standard mouse arrow or an outlined char cell box
> for the mouse because these are easier to use than the I-bar.

Too late, it already works this way in the recent versions.

> If the mouse button is clicked whilst the mouse is on, then the cursor
> should move to the character cell nearest to the mouse pointer. BUT....
> listen to the echo from the host after each cursor arrow code is sent -
> then the cursor can be 'stopped' if it exceeds the selected position
> (as is the case if there is tabs between the original cursor position and
> the destination position selected by the mouse).

And how do you suggest to do this? (It's not so simple as you think it
is...) There are about as many different ways to postition the
cursor, as there are editors, the way it's implemented now, it works
ok with xedit and with edt (without tabs).

> But we can't.

Wrong, what "romero" obviously does not realize is that whenever one calls a
bulletin board and downloads programs, the same problem may occur--the
program may be a trojan horse program and trash the hard disk, etc.

The fact that there is a system operator in charge of the bbs does not
stop these occurances. Many sysops do not have the time to test out
every feature of every program which is posted to their board.

I find it hard to believe that someone is going to take the time to
archive, uuencode and upload a trojan horse program to the net.
Maybe it is my trust in people, but I don't think it is going to happen.
I think we can trust the fellow netters out there.

I didn't ask for it. You are certainly entitled to your
opinions, but WHY would you post this to comp.sys.atari.st?
Are you trying to stir up some excitement, or what?
If you guys want to rant and rave about stupid things like this,
why not keep it to yourself? Mail is good for that, you know.

>Configuration: 1040 ST with 20MB SH204 hard drive, Magic Sac+Translator box
>the Hard disk has 3 ST and 2 Mac partitions (created with Magic Sac).
>When he tried to use Uniterm 2.0a 20 (from floppy) when Uniterm came up it
>destroyed the Mac partitions on the hard disk (ST partitions ok).
>He recreated his Mac partitions but every time he run Uniterm the partitions
>were destroyed.
>He then switched back to Uniterm 1.8a20 and everything worked fine.
I find this VERY VERY VERY VERY VERY VERY VERY VERY VERY VERY VERY VERY
VERY VERY VERY VERY VERY VERY VERY VERY VERY VERY VERY VERY VERY hard
to believe, UniTerm DOESN'T start itsself, it's GEMDOS...., UniTerm doesn't
write to ANY disk without human intervention and you really want me to
believe that UniTerm suddenly bypassed GEMDOS and just for pleasure used
a BIOS call to destroy those nasty Mac partitions (and I can assure you
UniTerm uses GEMDOS for all disk operations) (oh yes and changed the
current drive by itsself aswell.......).

but not THAT strange!

2267. Multi-Bashing

Newsgroup: comp.sys.atari.st
Date: 1988-03-06 04:00:00 UTC
From: TCORAM@UDCVAX.BITNET
Message-ID: <8803060401.AA21207@ucbvax.Berkeley.EDU>
Source record: 253966

Aside from the RTX slant of the Multitasking discussion...what exactly makes
a ST a ST? I mean, is a ST without GEM/GEMDOS/TOS still a ST?
I want multitasking, but I STILL like my ST. I don't want an Amiga....
Lots of Amiga owners seem to be posting the 'AMIGA does this...' type of
messages to this digest. Sure, the AMIGA has a better OS than the ST
(who doesn't? ;-), but a machine is NOT tied to an OS. If you don't like
TOS, through IT away (not your machine). What all my soapboxing is leading
to is this:

Can anybody post reasonable descriptions of OS alternatives to TOS?

Like OS-9, MINIX, etc...??

Which brings me to a few questions:

Just how UNIX compatible is the C compiler for OS-9 with UNIX? They say they
are source compatible in thier ads... Does this mean I can REALLY port C
stuff (forking and all) to OS-9? Or is it just 'file' function compatible
with UNIX (as is most decent C compilers seem to be)?
I am thinking about OS-9 (68 Micro Journal is talking about covering STs now).

I seem to get the feeling that quite a few people out there waiting for MINIX
for the ST (it is coming in late spring) expect more of it than what it will
probally deliver. If it is anything like the implementation on the IBM PC,
then it will not be *THE* multitasking OS for all ST users. MINIX is great
for experimenting and playing with, but it will probally never become the
standard multitasking OS for the ST that everyone is looking for.
MINIX will probally be for hacking (I can't wait to get a copy ;-)...
What do you think?

BTW, this wasn't meant to be a FLAME on anyone or any machine... I work with
AMIGA fanatics, ST fanatics and (ugh) PC fanatics and they weren't offended
or outraged by anything I have said. ;-)
(If I say that I don't want an Amiga, or think that thier OS is unreliable
and buggy, will I be flamed on INFO-ATARI by Amiga owners??????)

2268. Lattice C vs. Megamax

Newsgroup: comp.sys.atari.st
Date: 1988-03-06 04:24:00 UTC
From: TCORAM@UDCVAX.BITNET
Message-ID: <8803060434.AA21756@ucbvax.Berkeley.EDU>
Source record: 253967

I am looking for some input on C compilers here... I have LATTICE C (not the latest version) and MEGAMAX C. As awful as some people say that LATTICE is on the ST, it has one thing going for it... you can port to it. When I write portable code (hah!) on my PC or VAX/VMS, I can port it easily to LATTICE C. Megamax is hopeless. It just doesn't have enough functions. LATTICE is missing some functions that are available on the PC versions, but it has quite an extensive function library. (Some of the missing things include TIME functions and variations on exec()). Sure, LATTICE is slow and produces HUGE binaries...

The question is this: Is Mark Williams C for the ST comparable to Let's C on the IBM? It has a REAL honest to goodness decent function library! I have seen rave reviews of the compiler in this digest, but how does it really compare with the IBM PC compilers? After years of people drilling portable code design into me, I find that I have trouble porting to the ST. Even if I have machine dependent parts in my code, knowing that my ST compiler can support TIME functions and stuff like temporary-file functions, can really help in porting.

BTW, does any ST compiler support SIGNALS? (like trapping ~C and other interrupts)

Looks like I'm the new moderator of comp.sources.atari.st and comp.binaries.atari.st. I don't have the archives yet (I'm expecting a magtape in the mail within a couple of days). The archives will be located at ssyx.ucsc.edu (128.114.133.1), but will not be available for anonymous ftp right away, as we're connected to the net at 9600 baud (we are getting Ethernet within a couple weeks...) Please, don't ftp here until I say everything is all set up -- our net is slow enough already! If some of you just can't wait to get your submissions in, you can mail them to me here; Usenet should know about me soon, so postings to comp.{sources,binaries}.atari.st will go to the right place (namely, my mailbox).

I'll introduce myself more fully once I'm officially installed as the moderator. Hopefully we can get lots of nifty programs flying across the net. Gentle[wo]men, start your compilers!

" Just because it's 8-bits doesn't make it obsolete. ==== == ====

Whether people buy a magazine solely for the type-in programs and whether
a magazine has ever persecuted [sic] anyone for pirating their programs
isn't the point. The point is that magazine programs are protected by
copyright just as much as any other program. Frankly, I find the attitude of
this article frightening. I had heard that developer's were dropping the ST
due to rampant piracy, but up until now everyone I knew took software
piracy very seriously. Please, for the sake of fairness to those who produce
the programs, those who purchase legal copies, and for the sake of encouraging
support for our computer, do not tolerate software piracy, no matter how
minor it may appear.

2274. Re: fsel_input

Newsgroup: comp.sys.atari.st
Date: 1988-03-06 17:07:35 UTC
From: braner@batcomputer.tn.cornell.edu
Message-ID: <3951@batcomputer.tn.cornell.edu>
Source record: 253974

[]

Lambert Schomaker posted some ideas on how file selection could be done
in a completely different manner from the "fsel" dialog box.

Another example is the file selector box in the Laser C shell, which is not
at all the standard GEM box. It has a small window with the filenames listed
in it. Directory names have an "open" button next to them, just like they way
they appear in the desktop when one chooses "view in text". Double-clicking
on a directory entry opens the directory. Clicking on a "close" button at the
top left corner of the window closes a directory, returning to it's parent.
If the directory displayed is the root directory of the drive, clicking on
the "close" button displays a directory of drives, like this:

<> A:
<> B:
...

(The <> is supposed to mean the standard "open" button.)
I like this arrangement since the whole thing is compact, and operates
in the same conceptual way the desktop does.

In contrast, two alternative fsel boxes posted recently (under the names
"filefix" and "itembox") add a button for each drive. That's just clutter
in my view. I do like the nice touch of requiring only one click (not a
double-click) on directory names to open them. The PD one of the two
("filefix") is buggy, though: it works fine the first time, bombs on the
second (at least if anything unusual happenned the first time).

My biggest complaints about the GEM fsel box have NOT been addressed by
the posted alternatives. Here is my wish list, if anybody who's into
writing such things wants ideas...

The drive:\directory\subdirectory*.* entry drives me nuts.
For one thing, the "*.*" should be the default, without the need
to type it. Then there's the very limited editing of that string.
If it says "A:*.*" and I just want to change the 'A' to 'B', I have
to press ESC to clear it all, then retype the whole mess. Why can't
I position the cursor anywhere in the string with the mouse, Mac style?
(yeah, I know, Apple's lawyers would get mad...) If the "*.*" was
implicit it wouldn't be so bad.

Then comes the worst part. After laboriously typing in the path, I
ALWAYS, automatically, without any thought, hit RETURN. Which kicks
me out of the fsel box, and I have to start all over again. Why, oh why,
can't RETURN, at that point, be equivalent to clicking inside the directory
list? After all, at that point I already have the fingers on the keyboard!

Other suggestions: can't I be a masochist (?) and simply type the full pathname, including the file name, into ONE text-edit input field, if I so prefer? Why can't the thing remember where I was last time around (the application, really, should do that) (well, "filefix" tries to do that, but if my last attempt involved typing in a nonexistant path, it refuses to let me in at all the next time).

Enough bitching. I'll sign off and return to the UNIX shell... :-)

- Moshe Braner

2275. GNOME 2.0 ready

Newsgroup: comp.sys.atari.st
Date: 1988-03-06 18:24:42 UTC
From: braner@batcomputer.tn.cornell.edu
Message-ID: <3952@batcomputer.tn.cornell.edu>
Source record: 253975

[]

Last year I distributed (via snail-mail, on disk) my very own version
of microEMACS, for the Atari ST (and also for UNIX).

I use this editor daily for all of my work, including program editing,
some data files, shell scripts, letters, and word processing (in combination
with YAFIYGI ("you asked for it you got it") style typesetting software, such
as TeX or troff). I am writing this very posting in it. Its strongest
advantage is that I can use it on every system I need to work on. It does
not support GRAPHICAL windows (has text-only output) but it supports the
editing of multiple files in multiple windows. The edited files must
completely reside in RAM, but the editor can use all available RAM.

I have just finished another major revision. It now compiles on UNIX
(I tried BSD 4.3 and Gould UTX 2.0 (?)), the Atari ST (Laser C), and
(new!) *** MS-DOS machines *** (Turbo C 1.5). The latter two versions
make extensive use of the function keys of the respective machines.
The source code is common to all versions, with system-dependent stuff
inside conditional compilation switches. In theory it will also
compile on VMS and CPM, but I havn't tried that.

The nice features of my version include:

1) It's one compact self-contained executable file (about 55K).

2) It has instant built-in help.

3) The function-key support means little use of control-keys is necessary.
(The standard control-key command invocations are retained, though.)

4) Horizontal scrolling for long lines (up to 255 chars).

5) All parameter entry requests (e.g., search patterns, file names,
buffer names...) have intelligent defaults through which one
can scroll with up-down arrows. Each can be screen-edited with
the usual keys (left-right arrows, delete, backspace, etc.).
This makes for very quick respones with minimal typing.

6) Command line option (default ON in UNIX version) to save all keystrokes
in a file (flushed every 256 keystrokes). The file pathname is taken
from an environment variable. This is to recover work after a system
crash.

7) Search patterns can include a '.' wildcard (fits any char), a
"whitespace" wildcard (^W, fits any amount of whitespace, including
none), and '!' that means the next char can be anything BUT what
is in the search pattern.

8) 8-bit extended ASCII supported (in ST and MS-DOS versions): preceding a key with Alt-A sets the 8-th bit. Such chars are displayed in the extended system font. In disk files, 8-bit data are read and written correctly. The help facility includes a built-in table of these chars.

9) The MS-DOS version uses DIRECT screen output (courtesy of Turbo C 1.5), with a command-line option to force BIOS output in non-100% compatible machines. The latter is fast, the first is even faster.

10) Word wrap and paragraph reformatting. Margins can be set from the command line or inside the editor.

11) The number of rows and columns to use is settable from the command line. Useful for slow over-the-modem use and with windowing terminals.

12) In ST and MS-DOS versions: low-level binary block file I/O, MUCH faster than the original microEMACS.

13) In MS-DOS: escape to COMMAND.COM for a shell or for one command. In the latter case, the default-entry facilities create a pseudo-shell with screen-editing of previous commands, intact across separate accesses to this command (Alt-Z).

14) Search for matching brackets, recognising nested (), [], and {}.

And so on.

I have changed the name of the editor to "GNOME" (Generally Not the Original Micro Emacs). This is in compliance with Richard Stallman's request that such things not be called EMACS (he wrote the original, in LISP). Also to identify my version (which, by now, is mostly my code!) from the numerous other versions of "microEMACS" around. The current version is GNOME 2.0.

Since the source code is about 190K, and each executable about 55K, I think that posting it is not a great idea. Any suggestions on how to make it available? (It is copyrighted but I don't mind people using it for free!)

For now, if you want it quick, send $5 to me (to cover my time and expenses) and I'll send a disk in physical mail. Please specify 3.5" (single or double sided, the latter MS-DOS 3.2+ compatible) or 5.25". Sources (in C) will be included (ARCed). Overseas requests: please send several disks instead of money. I would rather not send it e-mail, but I'll put it up for anonymous ftp if somebody can explain how you do that.

- Moshe Braner

PS: Much thanks to Dave Conroy, who wrote the original "microEMACS" (in 1985, I think), and passed it around!

Please, don't get me wrong. I don't support piracy, and I certainly don't subscribe to the "all forms of data must be shared" school of anarchy. It's just that I have this (skewed?) view that an issue of Antic is no different from an issue of Time, and if I can send a photocopy of a Time article to a friend with no problems, then what's the difference with a type-in program...

Like I said, though, I mean no harm.

--R.J.
B-)

P.S. Moot point: The "Please do not distribute copies of our type-in programs" disclaimers in Antic/Analog/etc. are kind of obscure, if you ask me. I never even notices those messages until I was leafing through all of the small print in Antic the other day...

>Richard K. Lloyd,

all these points are valid and true....

having been a developer on the ST for almost 2 years, and having battled
to understand this sucker, and having invested both huge amounts of time
and $$$ (3 1040s, 2 HD, 5-6 monitors.....) i have to agree that the ST is
not the "ideal" development machine. the only thing that keeps me going

is the fact that there ad 500k+ machines out there. otherwise i would surely switch my efforts to a more "favorable" host/manufacturer.

i hate reading flames Re: how bad ST is vs how good Amiga is (and visa versa). that's not REALLY the issue. what is important is to whip atari into shape ("i'm mad as hell and am NOT going to take it anymore..."). atari SEEMS to be going after mac II/sun/etc... market but is woefully ill equipped to do so. their org chart is so lean that if Cindy C. is out, the entire dev support structure STOPS TO FUNCTION! i have had tremendous problems with SH204 drives (atari sent me 2 in the past 2 weeks, both bad, and i spent $150 in fed exp charges to get them, and now they are COMPLETELY OUT OF STOCK!!! i was left to contact a local rep to see if he could get one from a local store...that's not MY idea of support, especially for developers).

as a businessman, i have to make a decision: keep on my current masochistic path or switch to a friendlier environment. it's hard to throw away time and $$$ investments (especially time...) but i'm really starting to look at that as a serious option.

atari (or at least most of the people i deal with) means well. but their current posture really is one of a mass market distributor. they will never sell anything to fortune 1000 firms in the $5-10k range w/o support and they desperately need to have support, starting with developers (you know, the ones who make the software that sells the machines).

boycotts are not a solution, either. i, for one, am writing to L. Tramiel with my feelings, as an interested participant in atari success/failure. i suggest we all do this, not as a plea or threat, but rather as a source of information and market sentiment. afterall, the people on this net are more likely to recommend/purchase a $5-10k workstation than the average consumer/hobbyist. if atari sells >20 copies of the ABAQ or whatever to nonprofessionals, i will indeed be suprised.

if you want to further the cause, don't waste time flaming amiga. it is a fine system for what it is, just as STs are fine for what they do. Remember: atari came out with the ST as a low-cost yet powerful machine. you generally get what you pay for. the issue is really how serious are the Tramiels and major stockholders and can they be influenced to react to a few hundred (thousand?) letters from netland. The Tramiels are wealthy; they can always go out and start/buy another company and will always have a market eager to buy their wares. it is our problem to make sure we get what we want. that's how a "free" market works.

-bill

In article <898@aucs.UUCP>, 870646c@aucs.UUCP (barry comer) writes:
Hi all, well Atari finally sent me my blitter chip(thank you ATARI), but there
seems to be a problem with Assempro now. Whenever I try to assemble some
code that accesses the tos.l file it loads and when it comes to the GEM_INIT
command I get box telling me that everything is messed up?????
I reassembled the tos.l file, and got no difference. Can anyone help me out,
I need my assembler!!!!!!!!!!!!!!!!!!!!!!1
later
Barry

Have you tried turning off the blitter from the desktop? Most ST
wordprocessors crash when the blitter is turned on, run OK with it
turned off.

"What's a word processor?"
"Well, you know what a food processor does to food?"

2282. Re: System vars, Linking

Newsgroup: comp.sys.atari.st
Date: 1988-03-06 21:58:30 UTC
From: rosenkra@Alliant.COM
Message-ID: <1351@alliant.Alliant.COM>
Source record: 253982

regarding the topic of linking and compilers:

i have been using the original devkit compiler/linker (i.e. Alcyon) for
almost 2 years now. yes, yes i know that mwc:

1) is faster at compiling
2) makes smaller executables
3) documented (:^)

i have had only limited experience with mwc v1.x and (eventhough i used to
live in Chicago not far from mwc hq) i still prefer alcyon (i'm generally
using v4.14). does mwc support bit fields? how about LARGE arrays (>64k)?
i know when i was shopping megamax did not and mwc was not around.

anyway, with the advent of aln (thank you Mr. Pratt...), alcyon is at least
bearable (acutally pretty good, if you know the traps :^). alan released
aln to me generally early when the project i was working on could no longer
be linked with link68 (just tooooo B I G).

my only beef with alcyon (and it is a real annoyance) is with the inability
to redirect compiler msgs to a file (apparently it writes to CON: directly).
this is a major hassle since you have to watch the screen during EVERY compile.

i can only think of 2 ways around this: 1) set up a TSR which monitors
writes to CON: and redirects to a log file ONLY during compiles 2) hack
and slash the c{p,0,1}68.prg files to get them to use stdout.
obviously 2) is a real pain (and probably illegal). has anyone tried 1)
or another alternative? i spoke to alcyon and they have no remedy (i asked
for src to do it myself :^). did they write gemlib? if so this is especially
stupid. does anyone know if mwc now outperforms alcyon (v2.x or new v3.0)?
seems like i remember it was slower in execution than alcyon, my highest
priority.

i generally use a homegrown cc and a (modified) make that (i believe) was
originally posted on the net, gulam the shell of choice (though i wish
it had pipes....).

thanx a priori...

jrd@STONY-BROOK.SCRC.SYMBOLICS.COM (John R. Dunning) writes:
>
> Is there anything that can make use of the symbol
>info in an executable?
Of course, SID (comes with Atari's Dev Kit) does it. I don't like SID too
much, but when you've got no choice, it's better than nothing...
We've used it a lot when we ported Smalltalk-80 to the Atari. We used the
C-compiler on a unix system (to minimize portability hassles) and converted
the binary into the Atari executable format (all on the unix box).
Only the binary was tranferred to the Atari.
>
>Also, when one loads an executable, where in memory does the symbol info
>get loaded? Does the TPA point to it?
nope, it is not loaded when a program is executed normally. Only debuggers
should read it in and make use of it.

Hans-Martin

PS: how many other language systems for the atari produce symbol tables
or have a debugger capable of reading it ?

From: Dave_Ninjajr_Flory@cup.portal.com
Message-ID: <3728@cup.portal.com>
Source record: 253984

Just a small warning if you use Zoomracks II. It will not function with Diskfree. With diskfree loaded ZR will not save to disk. This is real nasty as it will read in your file and then after you have worked on it perhaps for hours, you find you can't save to disk. The first try will rename the original file to backup and create a 0 bytes file. The second try eliminates the backup and makes another 0 byte file. If you don't have a backup of the original file, you are &^()* out of luck.

2285. Re: Lattice C vs. Megamax

Newsgroup: comp.sys.atari.st
Date: 1988-03-07 10:08:52 UTC
From: pes@ux63.bath.ac.uk
Message-ID: <2265@bath63.ux63.bath.ac.uk>
Source record: 253985

Well, since you say you have Lattice C, but not the latest version, I'd suggest that the first thing to try is getting an upgrade. 3.04 has a greatly expanded library over the earlier ones, runs a bit faster, and produces much faster code. Probably cheaper than a whole nother new C.

> I didn't ask for it. You are certainly entitled to your
> opinions, but WHY would you post this to comp.sys.atari.st?
> Are you trying to stir up some excitement, or what?
> If you guys want to rant and rave about stupid things like this,
> why not keep it to yourself? Mail is good for that, you know.

Normally, I would have kept it to myself (and MAILed directly to the
person involved), but I was angry with the person who'd "flamed" me just
because I put a personal opinion at the end of one of my postings.
I don't like being accused of posting "childish bulls**t" and being told
to take a course in logic (???), so I thought other people should see
some extracts from his MAIL to me, along with some 'arguments' he requested
I supply...
Anyway, if you want to see a GOOD machine, forget the Amiga, Macintosh and
Atari ST - buy an Acorn Archimedes...I've been programming in ARM (RISC) code
for a couple of months now and it is BEAUTIFUL (so's the Archimedes - puts
all other machines below a MicroVAX 3500 to shame).

From: UUCJEFF@ECNCDC.BITNET
Message-ID: <8803071638.AA06966@ucbvax.Berkeley.EDU>
Source record: 253994

There from time to time are some requests for infos about samplers for the atari st. There is one that plugs into the cartridge port, it is formally made by Hippo, but now has been taken over by someone else. It is around $100. Do not even bother with this. It is noisy, you have about 4 bits of DC noise. And the software could be written better.

If you are serious, you are going to have to get something like a Mirage or ADAP or an Akai, and then get some appropriate library software or write you own. The thing about the ADAP is that you have to dedicate an ST to it, but it gives you CD quality, with 16 bits. Casio also makes a 16 bit machine, and I have heard them in clubs and they sound good. Beyond that, if you have $70K, you can start looking at a Synclavier and with 100 get a Fairlight.

On saturday (03-05-88) publishing partner professional was shown at the ACE meeting here in St. Louis. The head programmer and some PR guy gave the the presentation. The programmer, Darren (I didn't catch his last name) said the program was 90+% finished and he is working on some of the enhance features. He couldn't give a date as to when he would be finished;"depends on how much sleep I need in the next three weeks."

From what I saw of the program it is going to be fantastic. It does all the things you wished publishing partner could have done in the first place plus more.

The upgrade is supposed to be $50 plus $5 for shipping/etc.

Source record: 253997

Well I am new to the Atari world....so pardon me if I am greatly out
of line. We have all been waiting anxiously waiting for the ROM upgrades
from Atari. Why don't we, as responsible programmers, take this great
moment and standardize! Yes...silly as it may seem, now is probably the
best time to do it. With the new ROMs, may programs will have to be
reworked anyway, so why not standard certain things while we are at it.
Things like:
((Fonts....boy...this would be great
((Postscript driver....in fact...ALL printer drivers....
these are all I can think of off the top of my head....maybe you guys
can think of more.....think of the power this would give the average
user...
Perhaps standardization of programming techniques, ie...rules, that
programmer should stick to in order to keep compatability within different
programs......
I know...I'm just asking for too much....so flame me if you really want..

> compatible terminals has no provision for dealing with mixed length
> lines (I can think of all kind of perversions you would have to deal
> with, if you want to have a terminal with this feature).

Sorry Simon, but I use an HDS2200 (VT-220 compatible from Human Designed Systems), that *does* retain the screen on size change.

Actually, it's an option in the setup menus. When enabled, it does this:

Change from 80 to 132 --> extra 52 columns get spaces

Change from 132 to 80 --> lines get truncated at 80 (no wrap)

It seems to work just fine. The software may not deal with it particularly well (editors, etc), but that isn't the terminals problem, nor should it be.

I kind of like the feature, but then again I don't switch screen size all that often.

On editing the drive directory line:

You can use the arrow keys to edit the drive directory line. To change the
A to B move the cursor over the A, hit DELETE and type in the B. I do this
all the time. I do agree with you on the other points. Fsel_input is brain dead.
It took me a long time to get myself not to hit return after typing in the
drive spec.

Not from what I've heard. There's a local Atari-only store near L.A.
called Logical Choice, and they've been getting Mega ST's and other hardware
without problems. I've heard, however, that there is a shortage of ST's in
America in general (apparently they're going over to Europe, where everybody
is buying them like hotcakes [can anyone confirm?])...Seems us AmericAtarians
will have to wait awhile...

On a similar vein, Sam Tramiel/Neil Harris admitted on GEnie that they've
been neglecting the US market quite a bit, to focus on overseas sales...

2305. Re: Micro RTX Description (discussion, predictions)

Newsgroup: comp.sys.atari.st
Date: 1988-03-07 18:09:44 UTC
From: ttims@watdcsu.waterloo.edu
Message-ID: <4518@watdcsu.waterloo.edu>
Source record: 253855

Your RTX system sounds really, really nice. (I wrote my own mini message passing kernel for the Atari, but it has only a small fraction of the power of yours.)

So, considering that it exists, and that it sounds like it's in good taste, technically speaking:

Why isn't Atari licensing it from you and distributing it with all their machines?

It sounds like a better software system than they will ever be able to design and distribute. Are they holding out because they think they can do better? Is their management unable to appreciate the future marketing value of a message passing multitasking operating system (especially in a networked environment)? Are they simply unaware of it? Do they take the point of view (regrettably common) that they can do economically better by producing a poor product for less money?

Would you accept a binary licensing fee of say, 15 dollars (US) per copy for distribution with every Atari ST? If Atari was willing to simply pass this fee onto each consumer by raising the system cost by 15 dollars would this impact hardware sales in a meaningful way? (What would be a more optimal licensing fee?) Consumers, would you pay 15 dollars more for an Atari with RTX built in?

If it was distributed (and became the new Atari operating system standard) would this encourage more sophisticated software development for the machine, and would this increase the market for the hardware (and for the RTX)? Is it possible that RTX could add more reliability to stock TOS?

If your RTX would port nicely to a system with an MMU, I'd say it sounds like it could be the software salvation of TOS and the whole ST line.

I don't think there are any medium term prospects for personal computers that are not addressing the memory protection/multitasking/software reliability problems. The only primitive operating system that will survive will be MSDOS. The workstation manufacturers are showing cheaper and cheaper products that have worlds more functionality and reliability that current personal computers. More and more people are coming to understand the value of these types of machines and (like me) will demand that value in their personal computers.

There will be two choices for decent operating systems: UNIX, and anything else that implements the minimum technical niceties. I'm not saying that UNIX is the best, or even desirable. It exists, and it can be ported and it can work. The biggest obstacle to the popular acceptance of UNIX systems (with windowing) is the high, high cost of the application and system software. There is good application software out there for workstations: it would never

sell in the mass market unless the prices dropped by a factor of 10.

It's in this niche that "other decent operating systems" will fit. With foresight and planning, cheaper operating systems and software could be highly competitive (in terms of price/(functionality+reliability)) with more sophisticated workstations. Apple seems to have no problem understanding this. Foresight and planning means the development of RELIABLE and SECURE hardware and software. I think there is a better chance (technically) that the Atari could evolve into the budget workstation that the Apple. The Atari hardware and software is less crufty and cast-in-concrete than Mac hardware and software. (This is mostly because the software is more loosely organized, and because the hardware is cleaner.)

It think it would be very difficult to produce a Mac which one could leave turned on for large periods of time, and do useful work on, without being worried about memory corruption. I think that with intelligence and taste, TOS (with RTX?) could be made to operate reliably in a memory protected environment.

Reliability and functionality are the two things which sell machines. A user needs *both* to get work done.

> still a ST?

Well, I suppose that depends on the user. If a person is willing to use a less-well-known operating system, then for them the hardware is the important item. For other users, they want to continue to conform to the standard environment. The Coco 3 is a good example -- OS9 runs on it, but still lots of people use RS-DOS.

> Just how UNIX compatible is the C compiler for OS-9 with UNIX? They say they
> are source compatible in thier ads... Does this mean I can REALLY port C
> stuff (forking and all) to OS-9? Or is it just 'file' function compatible
> with UNIX (as is most decent C compilers seem to be)?

I used the 6809 version of OS9 a while ago. Since they are multi-tasking, they do have techniques to spawn concurrent tasks, but as I recall, their names for these things was different. However, I suspect one could easily put together a Unix compatible library.

> I seem to get the feeling that quite a few people out there waiting for MINIX
> for the ST (it is coming in late spring) expect more of it than what it will
> probally deliver.

Well, of course we won't know until we get it. But, as long as it is fairly Unix compatible and supports the midi and serial ports, I'll be happy.

> MINIX is great
> for experimenting and playing with, but it will probally never become the
> standard multitasking OS for the ST that everyone is looking for.

As I mentioned, OS9 is the multi-tasking system of choice on the Coco, but I think the ST version is too expensive. The $150 personal version doesn't include the C compiler. To get that you have to go to the $600 Professional version. I wish they would offer a lower cost version without Basic09 but with the C compiler.

As for the hacking of Minix, well I suspect one of the first things people will try is to get a windowing front end for it. I hope that we'll be able to make calls to the line A routines in ROM when Minix is booted.

```
From article <2794@dadla.TEK.COM>, by jrb@dadla.TEK.COM (Jim Binkley):
> command = "\\bin\\date.prg";
> args = " 200001322400"; /* note the blank :->... */
> pexec(0,command,args,"PATH=\0");
>
> What happens when we say "PATH=\0"?

What happens is you are explicitly passing the perfectly legitimate
environment consisting of one variable, PATH, which has no value.
The \0 is the null byte ending the PATH value, and C puts another
null after that to terminate the string -- the double null
is the end of the environment.

The environment (as defined by UNIX and used by Atari) consists of
strings separated by nulls, with a second null after the last one
which terminates the whole environment.

Conventionally, the "strings" mentioned here are of the form

name=value

where name (usually all caps) is called an "environment variable" and
value is its value (arbitrary text). For instance,

MAILER=/usr/ucb/Mail

is one environment variable which tells anybody who cares to ask what
program to use to send mail.

The point of the environment is to communicate things to programs
which you don't want to have to say in a config file or on the command
line, like your name, your home directory, what shell you're using,
etc.

Does this answer your question?

>
> My point is: don't be mislead into thinking that a Pterm handler is
> nothing more than a simple longjump.

It *is* just a simple longjmp! (Except that it gets executed in Super mode -- but the handler can just consist of a longjmp.) If you have a global pointer (like an extern or your DTA) pointing into your stack, and you do a longjmp, it still points to your stack (or where the stack will someday be). It's up to you not to use those pointers -- in the case where the ^C might occur while the DTA is on the stack, your Pterm-recovery routine should reset the DTA to somewhere else.

On the other hand, since the DTA is only used for Fsfirst/Fsnext, you should explicitly set it before each round of calls. Then you're sure to be safe from DTA fever.

Other globals have always had that problem, though: if you longjmp, you have to be sure you reinitialize them.

The normal program loader discards it. SID and DDT load programs differently,
and keep the info around.

I bought my 1040 ST from CMO, and it was prompt in being sent (everything
was in stock :-), but if you order something that is not in stock, it
can take forever to get it. They don't seem to really know when an
item might be in stock again.

No panic here. But it is true that the author of the original DOS portions
of the Amiga OS (generally considered in the Amiga community to be the parts
most needing rework, and in fact which have been reworked), Tim King, is the
guy responsible for the Abaq software.

Hmmm, the last such "enhancement" was the infamous blitter (which still
has to arrive anywhere in mass quantities). As I've stated numerous times
before, I don't doubt the qualities of Atari engineering, but Atari still
has to show us that they can get an actual product up and going. And as
always there is the question of software support, will Atari mangement
make an official statement about a bug fixed GEMDOS version as an example?

Matter of fact, the german computer magazin c't has published a series
of patches for the ROM's that allow you to run most (they claim 99%)
programs with their 68020 board. They use some of the unused Line-A
"instructions" as replacement for the Line-F trap. The main problem is
that you really don't get so much more speed (they claim about 50%)
for the money (if you can use the 68881 you're naturally lucky).

Now that Mr. Beckemeyer (a good guy) has made this extremely valid point about Mark Williams Company (also pretty much good guys), maybe some readers of this group will pause for the odd nanosecond before flaming Atari (hiss the villain!!) for not having shoved "fixes" out of the door while they were still warm on the coding pad.

2320. Laser C question

Newsgroup: comp.sys.atari.st
Date: 1988-03-07 23:21:15 UTC
From: koreth@ssyx.ucsc.edu
Message-ID: <2234@saturn.ucsc.edu>
Source record: 253871

I'm porting a program (BB/ST, my bulletin board system)) to Laser C (from Megamax 1.1). All the C stuff compiles without a hitch, but the inline assembly is a bit different. In particular, I need to know how to reference a label defined in an inline assemble segment, from the rest of the program. This code worked on the old compiler:

```
extern foo();

asm {
foo:
clr.l A7
rts
}
```

You could call foo() from another part of the program. That doesn't seem to work in Laser C. My other question is probably closely related; I want to install some trap handlers. The code

```
lea trap1hand(PC), A0
move.l A0, 0x90 ; or whatever address
```

worked in Megamax C; now it says "trap1hand undefined", even if it's defined in the same asm{} block. I've tried taking away the "(PC)", changing it to move.l #trap1hand, 0x90 (which would be the ideal way to do it), and a couple other things, to no avail.

Any help would be appreciated.

Idris supports some of the VDI calls. Any that do line drawing are supported.
The AES is not supported since AES and the Idris kernal contend with one
another. I can not speak for OS-9 and Minix but would assume they can not
provide AES support either.

From: Jim McCabe JEMCCABE at MTUS5
To: INFO-ATARI16 at SCORE.STANFORD.EDU
Subject: OmniRes ST

I'm considering buying OmniRes ST (a program from E. Arthur Brown Co. that lets any monitor run in any resolution). I remember someone a while posting a little review of it, but can't seem to locate my old digests.

I've got several questions about this product, and would appreciate any response:

a) how good is the color emulation on a monochrome monitor? Especially, on an intricate multicolored background, is it distinguishable as anything other than a mess?
b) how fast is this color emulation? Or, how good is the image in a faster mode?
c) are color register updates performed? (like in Degas's color cycling animation technique)
d) how smooth is the mouse movement when pretending to be a color monitor?

This sounds like an interesting product (not nearly as interesting as the late ST Video Box, unfortunately...)

If anyone else is interested, I could concatenate all the responses into a file and send them out. (That is, if someone answers this! ;)

In my younger years I would have sprouted bright blue actinic sparks
and gone for an artery. Instead I'll just say that "I was there, and
you were not." We did SO do it in six months. I'm sure it shows.

(At one early point, the ST was going to be a National 16016 or something.
The ST was essentially designed by Tramiel Technologies Ltd (TTL), oh, days
and weeks -- maybe even a whole month -- before KUJ signed the Warner deal).

When the Flying Tramiel Bros. took over the company, I was a mere (mere?)
video-game writer in a management-impoverished (though manager-rich) part
of the 8-bit games group. One fine, black day Leonard Tramiel and John
Feagans strode into the coin-op engineering building, hatchets and hoods
and clipboards in hand. While they were walking down the corridor, a voice
cried out over the announcment system:

"Imperial storm-troopers have entered the base! Imperial
storm-troopers have entered the base!"

We each had a two-minute interview to save our jobs. FTB kept fourteen out
of sixty or so engineers. Very entertaining. I don't think any of us had
much 68000 experience; they were looking for slaves. In some respects the
people who were layed-off were the lucky ones....

-Landon

[Disclaimer: Leonard Tramiel and John Feagans are perfectly nice people who
are NOT storm-troopers and who would NOT do anything nasty to anyone else
with a hatchet, though perhaps with a clipboard... :-)]

A program called VDU_2_0.PRG has been posted to the FILESERVers at CANADA01 and UHUPVM1. It is claimed that it will cure the 'Boot sector' virus and immunize the disk from future infection with this virus.

Does anybody have any information about this virus, its mode of infection, mechanism, symptoms or how wide-spread it may have become?

Please post replies to the net. Most people will be interested. /JT

>--
>Tim "The Enchanter" Northrup

This "change size without clear screen" feature is also
found on the Wyse wy85 terminal (and, I believe, another vt2xx clone
made bye some company called Draco I believe.) True, it would be a nice
feature to have, but admittedly not one that I'd die without. :-)

I have been following this discussion, and if there is one
thing that I'd like to see (maybe this is in 2.0, I only have 1.8 as of
yet, and am looking for an arpa/uucp/ftp archive for 2.0) is a small
editor, perhaps in a window, that would allow one to edit a small file
while still on-line (without leaving Uniterm.) This is the only feature
of FLASH! that I haven't seen Uniterm sufficiently beat the hell out of.
(As far as I am concerned, I have never seen such a nice term package as,
Uniterm, commerical or otherwise, including Procomm for the PCs, a nice
program in its own right.)

Thanks again for Simon for making the world, at least the world
of ST, a bit of a nicer place.

You don't need to clear the whole string. You can position your cursor using the arrow keys (cursor back and cursor forward only, since cursor up/down will take you to the next/previous field - or the other way around). The arrow keys are nondestructive and allow you to change the drive spec without killing the whole line. It's not very elegant (as a matter of fact I hate it) but it's possible.

Wrong.
If you get a good soldering iron
someone who can handle it
one of each HC00, HC139, HC573
lots of wire
and the german magazine ST Special
you can make an upgrade to 2.5 M with 41256-12 chips (48 of them).
It works. A friend of mine is working on a board for the chips so you don't
need to build stacks of 4 chips..

Since I don't know how to respond to your BITNET address, I'll
use this expensive method of answering - maybe it'll help others.

Sometime ago I moved my U.S. model 520ST to Europe (Holland).
I sold my color monitor, since I wasn't sure if the 60Hz refresh would
give visible 'wobble' when supplied from a 50Hz net, but figured that
the (70 Hz) monochrome monitor shouldn't care about its power frequency.
In Holland, I acquired a 220 -> 110 Volt transformer (In Holland, you
should ask for a 'VERHUIS TRANSFORMATOR' in an Electronics components
store - 300 Watts or more should do the job).
The safe way to test if things work, before risking your ST, is to
wire the transformer according to the instructions and connect a US
type lightbulb as load. Measure the voltage, which should be around
112-125 Volts (usually, you can use one of several taps to set the
secundary voltage. I managed to get 117 Volts that way - a safe bet).

The ST and monochrome monitor worked perfect from this supply. Also you
can run a European color monitor at 50 HZ from your ST using a so called
ST to SCART cable (and a TV with SCART input). This however requires a
program (or ROM patch) that sets your ST vertical rate to 50Hz. Any home
computer club there can get you one, since Atari forgot this little fact
with an earlier ROM release.

I used this setup for 1 1/2 years without problems (and then moved back).

Hope this helps,

Gert Slavenburg

2337. Extend you ST's screen into the border...

Newsgroup: comp.sys.atari.st
Date: 1988-03-08 19:04:43 UTC
From: unpowell@csvax.liv.ac.uk
Message-ID: <485@csvax.liv.ac.uk>
Source record: 253888

EXTENDING THE ST SCREEN INTO THE BORDER

You may have seen programs on the C64 that "removed" the border, at the top and the bottom of screen. This is possible on the ST. It's not really a new discovery as I worked out how to do it during Easter 1987, but recently I've seen a few programs by other people using it, so I thought I'd tell the rest of the world about it.
It is quite a simple procedure to produce this effect. While the last raster line of the normal display area is being displayed set the ST in 60Hz mode. Then wait until the next raster line and put it back into 50Hz mode, simple! The border at the bottom of the screen will "disappear" and the memory following the normal display area will be displayed down there. This really works best on a TV as there is a lot more space below the picture on a TV. I hear all you people in the States saying "but we're already in 60Hz mode", well I know that. I have never used this on a 60Hz display, but maybe doing the opposite will work, ie. into 50Hz on last screen raster line and back to 60Hz on first "border" raster line.
Anyway the two source listings following will demonstrate this. The first is the proper way to do it, as it creates a perfect display into the border. The second uses a bit less processor time, but as you will notice the last 16 pixels of the normal screen are missing from the display. The second is given for people writing programs with not much time to spare (their programs haven't much time to spare that is), where the first method which takes up a whole raster line, will get in the way of other interrupts they have going.
They both use timerb to count the raster lines down the screen. Although they could just interrupt at the last raster line on the normal screen, by setting timer B data register to 199, they interrupt on every raster line to put the colours up, which show that the extra display lines just work like any others and that the HBL on these lines is just like on any other.
Although I only describe how to remove the border at the bottom of the screen, it can also be done at the top of the screen, but the method doesn't work with some televisions that can't handle a 60Hz display.
Other "strange" effects can be produced with the display. Changing screen resolution while the raster scan is in the physical display area can expand the screen's width, but more on this at a later date.

Method 1

This program interrupts on the last raster line inside the normal display, and then waits until the next HBL. When the next HBL comes it puts the ST into 60HZ mode and then delays for a short time until the raster scan is just into the next raster line. Then it puts the ST

```
back into 50Hz mode. This waiting means that the interrupt routine
takes up two raster lines, which can be a problem in some programs,
although this method produces the best display.

raster_line equ $40
global_colour equ $44
local_colour equ $48

clr.l -(sp)
move #32,-(sp) * Into super mode
trap #1 * very messily (who cares?)
lea $70000,sp

move.b #1,$fa07.w * enable timerb

loop bra.s loop * hang about

vbl clr $8240.w * pallette 0 to black
clr (raster_line).w * reset raster_line
move (global_colour).w,(local_colour).w * this gives
* the scrolling
* effect in the
* border
add #$89,(global_colour).w * increment
and #$777,(global_colour).w * global_colour
rte
```

```
timerb move (local_colour).w,$8240.w * set pallette 0
cmp #198,(raster_line).w * right raster line?
bne.s not
clr.b $fa1b.w * TBCR must be clear to allow next
* instruction to work
clr.b $fa21.w * TBDR=0 ie interrupt on next hbl
move.b #8,$fa1b.w * timerb back into event count mode
wtlp tst.b $fa21.w * wait for next hbl
beq.s wtlp
clr.b $820a.w * into 60Hz mode
move.l $40,$40 * Delay 76 clock periods
move.l $40,$40 * until scan is in border on next
nop * raster line
move.b #2,$820a.w * back to 50Hz mode
clr.b $fa1b.w * TBCR=0 for same reson as last time
move.b #1,$fa21.w * back to counting single lines
move.b #8,$fa1b.w * back to event count mode
not addq #1,(raster_line).w * increment raster_line
add #$89,(local_colour).w * increment
and #$777,(local_colour).w * local_colour
clr.b $fa0f.w * clear interrupt in service bit/byte?
rte * exit
```

Method 2

The second listing, which follows, interrupts on the last raster line of the normal display and immediately puts the ST into 60Hz mode. It then waits a short while until the raster scan has moved from the border into the screen display area and then goes back to 50Hz mode. For some reason (probably due to part of the display line being in 60Hz and part being in 50) the last 16 pixels of the last normal screen display line are completely left off from the display, which leaves the border colour showing through here. If you need the extra speed and can cope with this missing "word" then this is the version for you.

```
raster_line equ $40
global_colour equ $44
local_colour equ $48

clr.l -(sp)
move #32,-(sp) * Into super mode
trap #1 * very messily (who cares?)
lea $70000,sp

move.l a7,a0
moveq #-1,d0
move #40000/4-1,d1 * fill screen so
filllp move.l d0,(a0)+ * missing word shows up
dbra d1,filllp

move.b #7,$8201.w * screen to $70000
clr.b $8203.w
```

```
move #$2700,sr * take over the system (My favourite!)
clr.b $fa07.w * disable
clr.b $fa09.w * all interrupts
clr.b $fa0b.w * clear all
clr.b $fa0d.w * "pending"
clr.b $fa0f.w * clear all
clr.b $fa11.w * "in service"
move.b #1,$fa13.w * mask timerb
clr.b $fa15.w * mask none
move.b #8,$fa1b.w * timerb into event count mode
move.b #1,$fa21.w * want interrupt on every raster line
move.l #timerb,$120.w * set up timerb handler
move.l #vbl,$70.w * set up vbl handler
stop #$2300 * wait for vbl
clr.b $8260.w * low res (works just as well in medium)

move.b #1,$fa07.w * enable timerb

loop bra.s loop * hang about

vbl clr $8240.w * pallette 0 to black
clr (raster_line).w * reset raster_line
move (global_colour).w,(local_colour).w * this gives
* the scrolling
* effect in the
* border
add #$89,(global_colour).w * increment
and #$777,(global_colour).w * global_colour
rte

timerb move (local_colour).w,$8240.w * set pallette 0
cmp #198,(raster_line).w * last (on screen) raster line?
bne.s not198
move.l $40.w,$40.w * short delay, until
move.l $40.w,$40.w * scan is in screen display area

>-bill

If the PC-version of Minix is anything to go by, don't expect to run
any current ST software under ST-Minix. The whole point of Minix is
that it completely replaces the OS in the ROMS. It comes with a c
compiler, but don't expect to find any TOS or GEM calls in there.

Unless ST-Minix is going to radically change from the design decisions
made in the PC-version, don't expect to run any commercial ST software
under it.
Any comment from the authors?

2339. Copyrights and Coercion

I tried to keep myself from posting this, I know it will just encourage them to keep harping on the issue, but I just can't go on silently suffering their non-logical assertions. So ...

The issue is copyright infringement, software piracy, idea theft or whatever else you like to call it. My perspective is not whether such things are currently illegal, but whether there is coercion involved, and just who is invoking the coercion.

"Define your terms!"

Coercion - The initiation of the use of physical force, or the the threat thereof.

Fraud - (I will avoid defining the term fraud, except to say that it is non-passive -- it requires the initiation of some action.)

Theft - The use of coercion or fraud to obtain some value.

Is it possible for someone to violate the copyright law without engaging in coercion or fraud? Yes! In fact that is the most common form of piracy. Is such piracy theft? No! (By my definitions. Not by legal definitions which have nothing to do with logic.)

Is it possible for a copyright holder to enforce his copyright without the use of coercion? No! (In most cases.) Ironically the copyright holder who uses coercion to maintain his asking price is directly obtaining value by that act. The copyright holder is the thief!!!!

Your mission, should you decide to accept it is to show that my premises (definitions) are not robust, or that I erred in their application. (logic)

2340. Buying an ST, need info.

Newsgroup: comp.sys.atari.st
Date: 1988-03-08 19:20:18 UTC
From: ugthomps@sunybcs.uucp
Message-ID: <9135@sunybcs.UUCP>
Source record: 253891

Greetings,

I am about to buy an ATARI 520st and would like to procure some information
about the machine first.

1) Is the blitter being distributed at all with 520st's that are currently out
there and if so, where can I get one?

2) With the new 520st's the drive is internal, akin to and in the same box as
a 1040st. Is it still possible to get a 520st with the drive external,
and hopefully at a cheaper price?

3) There are several mail order houses out there. What are the bad ones,
the ones to stay away from, and the better ones? I would *really* like
to do this mail oder since it would be cheaper than buying locally,
but am mega paranoid about getting an ST that doesn't work.

4) I've heard of and seen the AVATEX 1200 modem before.. It seems to be
a very nice modem that can be had for $79-$95 (mail order to local prlocal prices). Is
there another modem of equal value at a lesser price?

I'm definetly set on an ST but neither do I want to shell out more than
$1000 for a color system with modem.

I've already looked in the local swap sheets :-) Nobody is selling...

- Greg

2341. ST color graphics upgrade in software

Newsgroup: comp.sys.atari.st
Date: 1988-03-08 19:29:32 UTC
From: wayneck@tekig5.TEK.COM
Message-ID: <2500@tekig5.TEK.COM>
Source record: 253892

Lets do a software upgrade to the ST's graphics. I'm willing to work on a program that will allow more than 16 colors per scan line and release it to the public domain so that it can be used by anyone. Some time ago I wrote a program that loaded the palette registers every scan line based on the line return interrupt. (Horizontal blanking interrupt) It had some problems due to sloppy timing, but it did get the job done. I had hoped that it would leave plenty of free time for other processing, but actually due to saving and restoring the registers it only left a few microseconds per scan line over.

Later I bought ColorBurst (some of you may remember), I was very disapointed. Then I bought Spectrum and I was very impressed. So seeing that spectrum had licked the timing problem I got to thinking again. Wouldn't it be great if I could use Spectrum pictures in my own code! So I need two things, first the file format of Spectrum pictures and second some code to allow more than 16 colors a scan line. Maybe someone out in netland can give us the file format. By the way I highly recommend Spectrum, and in no way would hope to reduce the value of that product. In fact if other programs could use Spectrum pictures I would hope that it would enhance the sales of Spectrum. If any of the Spectrum programmers are out there I would be interested in their input.

Anyway lets get down to business. After seeing Spectrum I knew it could be done so I thought about it some more. Then I wrote a program that ran a very tight loop and just look at the value of the screen pointer and saved the values in an array. Sort of an built in logic analyize. I going to do a better one in assembly, still the data I got back was interesting. There are 60 frames a second and 200 scan lines a frame. There is 2 to 3 milliseconds dead time between frames and each scan line in about 85 microseconds long. On the scan line 60 microseconds is spent during the display of the graphics information and about 25 microseconds is horizontal retrace. The ST already has some code executing during vertical retrace, but about 1.8 milliseconds if free.

Armed with that data I have a plan, and this is where I ask for help, maybe some of you will have better ideas. Remember I plan to release this code to the public domain, which means anyone can use it in any program, even for programs that they plan to sell.

Here is the plan. Since using the horizontal retrace interrupt gained me so little I decide to just use the whole screen time. (I sure this is how spectrum must work). The program would consist of the users program running in the vertical retrace period (about 10% of the time) and the display code running the rest of the time. It may be possible to strip out the current vertical blank code and get more time. Of course you may lose some things like the clock, but so what. During the screen refresh time all interrupts would be turned off and the code would be written so that the number of cycles through the color changer code would equal the number of cycles per scan line. Something like

the following:

User Program
Wait for vertical retrace free time
Set timer for 1.8 milliseconds (could be different than 1.8)
User code

Timer Program
Put ST is supervisor mode
Turn off all interrupts (ori.w #0700,SR)
watch the screen memory pointer until it starts counting
use the first scan line to sync code
for 199 lines
reload color registers as much as possible
Turn on interrupts
Wait for vertical retrace free time
Set time for 1.8 milliseconds
return to user code

There are several ways to do the color register reloading. The one I favor is to wait until the first horizontal retrace and then blast in new vales as fast as possible. Maybe use move multiple during retrace and move (a1)+,(a2)+ during the actual screen refresh to get even timing some one would know where on the line which color registers are valid. This would be simple and means that the file formate would be color register values for 320X199 picture and the pixels values for a 320X199 picture. Another way would be to use move quicks and actually have the program write a the color register changer routine. This is a couple of cycles faster per color change, but the code is much longer, plus the setup time would be longer.

So here are the ideas so far:

movq.l D0,#color data for 2 registers (18 cycles)
move.l D0,(A0)+ a0 points to color registers
etc.

Or just
move.l (A1)+,(A0)+ (20 cycles)
etc.

Also during horizontal retrace to get a full change over

move.m (A1)+,register set (104 cycles)
move.m register set (A0)+

I think there are about 680 cycles to work with, unless my spy program has a bug. Anyway it will be easy to find out.

Anyway any more ideas?

Thanks,
Wayne Knapp

2342. Re: Atari Advertising Idea

Recently on a cabled episode of AIRWOLF they showed a "computer center"
oof sorts in the mountain where they keep airwolf. Lo and behold the
keyboard to this computer center was an ST. Looked like a 1040 too.

Maybe if atari sold more computers to the movie business *wink* *grin*

Being home sick today, I took the time to prepare this file (credits
at the end).
------------------------- CUT HERE ------------------------------
880308

DESKTOP.INF
==========

1) #a - RS-232

digit meaning
1 duplex 0 = full 1 = half
2 baud 0 = 9600 1 = 4800 2 = 1200 3 = 300
(note: this may have more values to provide for the new
control panel which supports all baud rates)
3 parity 0 = none 1 = odd 2 = even
4 data bits 0 = 8 1 = 7 2 = 6 3 = 5
5 protocol 0 = X off, rts/cts off
1 = X on, rts/cts off
2 = X off, rts/cts on
3 = X on, rts/cts on
6 strip bit 0 = on 1 = off
(shouldn't this be called "stop bits 1 or 2"?)

eg. #a062120 - full duplex, 2400 baud, even parity, 7 data bits,
X off and rts/cts on, 1 stop bit

2) #b - Printer

digit meaning
1 type 0 = dot matrix 1 = daisywheel
2 ink 0 = black and white 1 = colour
3 pixel 0 = 1280 1 = 960
4 quality 0 = draft 1 = final
5 port 0 = printer (parallel) 1 = modem (serial)
6 feed 0 = continuous 1 = single sheet

eg. #b000000 - dot matrix, b/w, 1280 pixels, draft, printer,
continuous (not the most interesting eg)

3) #c - Control Panel Settings

The first 48 digits or first 16 sets of RGB triples represent the
colours to set. The fisrt digit in a triple is the RED value, next is
the GREEN and the third is BLUE.

The last seven digits represent the following:

digit meaning
1 mouse button response 0 to 4
2 keyclick 0 = off 1 = on
3 bell 0 = off 1 = on
4 & 5 keyboard response 0 to 46
6 & 7 repeat delay 0 to 21

4) #d - Unknown, probably reserved

5) #E - View and Option Parameters

The first hex value determines how files are arranged in the directory
and if confirmation should be requested before copying and deleting.

bit meaning
7 view as 0 = icon 1 = text
6,5 sort by 00 = name 01 = date 10 = size 11 = type
4 deletions 0 = proceed 1 = confirm
3 copies 0 = proceed 1 = confirm
2,1 unknown

The second hex value is the screen resolution (and from what I can
tell, whether the blitter is on or off).

digit meaning
1 blitter 0 = off 1 = on
2 resolution 1 = low 2 = medium 3 = high

6) #W - Window Info

There are 4 lines, one for each of the four windows that can be
opened from the desktop. For each line, the first two bytes are
the slider bar positions, the next two are the desktop screen
location and the third pair defines the window size.

The next byte is uncertain but this byte will take on a value from
$07 to $0a or 0. Zero would denote a closed window. These values are
most likely window handles.

The text string provids the default pathname for the directory.
Closing and reopening a window will restore the normal diectory.
The '@' is used to mark the end of the string.

7) #M - Drive Icons

The first two bytes are the (x,y) location of the icon and the
third is the type of icon to use.

00 = file drawer
01 = folder
02 = trach can
03 = program
04 = file

The $FF is an $FF which seems to have no purpose in life. After that
follows the drive name and text for the icon (12 letters max). The
second text field is uncertain at the moment.

8) #T - Trash Icon

Similar to drive icons except no drive name is given.

9) #D #F #G #P - File Icons

eg. #F FF 04 @ *.*@
#D FF 01 @ *.*@
#G 03 FF *.APP@ @
#G 03 FF *.PRG@ @
#F 03 04 *.TOS@ @
#P 03 04 *.TTP@ @
#G 03 04 GEMCSH.PRG@ *.SH@

The information for this section may not be accurate this is based on
both observartion and what I've read else where.

"The first #F and #D are said to represent folders and disks; their
"function is uncertian. [..] and they should be left untouched.

#D function most likely stands for DIRECTORY not DISK while the first
#F probably stands for FILE rather than FOLDER. Based on what I say
for the rest of the examples maybe someone can figure out what these
first two lines do.

From what I can tell, the first byte represents what icon should be
used to represent the first file string. The second represents what
icon/type of file is the second file string. The second file string
denotes the type of files attached to the first (ie. installed
applications). Or it denotes what to append to a command line.

#G = GEM executable
#F = executable with no parameters
#P = executable with parameters

eg. #G 03 FF *.APP@ @ - Any file marked with .APP extension is to
be considered as GEM program using a program icon (with no command
line parameter).

eg. #G 03 04 GEMCSH.PRG@ *.SH@ - When any .SH file is opened, execute
GEMCSH.PRG passing the specified file name on the command line.

eg. #F 03 04 *.TOS@ @ - Any file marked .TOS is considered as a character based program. This is the confusing bit. Here a 04 is passed but no second file string is given. All I can assume is that it denotes that the command line not be altered in any way.

So from the above I can only speculate to the following meanings as I have not tried them.

eg. #F FF 04 @ *.*@ - What constitutes a none executable, displayable file.

eg. #F FF 04 @ *.DOC@ - This to me means that I can "show" any file with a .DOC extension.

eg. #D FF 01 @ *.*@ - What files should be listed when a folder is opened.

eg. #D 01 01 GAMES@ *.PRG@ - This means to me that when I open a folder called GAMES, I should only display .PRG files in the directory.

10) Sample DESKTOP.INF

```
#a062120
#b000000
#c7770007000260070055200505552220770557075055507703111103
#d
#E 98 12
#W 00 00 0A 01 15 17 08 A:\*.*@
#W 00 00 20 01 15 17 00 @
#W 00 00 36 01 15 17 00 @
#W 00 00 38 06 15 0D 00 @
#M 00 02 00 FF D RAM DISK@ `@
#M 00 00 00 FF A FLOPPY DISK@ @
#M 00 01 00 FF B FLOPPY DISK@ @
#T 00 03 02 FF TRASH@ @
#F FF 04 @ *.*@
#D FF 01 @ *.*@
#G 03 FF *.APP@ @
#G 03 FF *.PRG@ @
#F 03 04 *.TOS@ @
#P 03 04 *.TTP@ @
#G 03 04 GEMCSH.PRG@ *.SH@
```

Most of the info provided here come from "Compute!'s Atari ST" April 1987, Issue 4, Vol. 2 #2. The bit on file icons comes from my own observations as the article had no answers about #F and #D. Any additions or corrections would be appreciated.

>- Moshe Braner

Okay, I am currently at work on a new fsel_input routine. There
are some things that I've done which I doubt I'll change, like:

This will be a completely new fsel_input. It takes a few more
arguments than the old one, so there's really no way to trap
for the old one and pop up this one. Which means, that you can
use it in your own programs, but existing ones still suffer.

I will include a string for a title (eg. Delete Junk), so you know
what you're doing.

There will be an option to sort the files in several ways, mostly
like the Desktop does.

Re-selecting the drive letter will be handled through two
arrow buttons (up and down through the alphabet).

Aside from that, since I'm not yet done, I'm open to suggestions.
I'll try to work in as much as possible, while keeping it compact.
When I'm done, I'll be glad to release the source. BTW, I am using
Alcyon 4.14, just in case those of you with different C compilers
need to know.

Email me your suggestions, and we'll see what happens...

>Sorry Simon, but I use an HDS2200 (VT-220 compatible from Human Designed
>Systems), that *does* retain the screen on size change.

Which means that it isn't VT-220 compatible. And will miserably fail any
compatibility test.
....
>It seems to work just fine. The software may not deal with it particularly
>well (editors, etc), but that isn't the terminals problem, nor should it
>be.

Oh yes it should be, since the HDS will tell the application, that it's
a VT-220 and the application will expect it (the terminal) to do EXACTLLY
what a VT-220 would do. How do you program an editor if you don't know
what the terminal is going to do? Ok, you say then it should send a response
saying it's a HDS2200 in this and that mode, BUT then it's no longer a VT-220
terminal is it?

BTW the HDS does not work the way the original poster described (the HDS
does NOT have mixed length lines, it just doesn't erase the whole screen
when switching modes).

(I don't really think this discussion belongs in comp.sys.atari.st, that's
why I've refrained from giving a LONG list of situations where everybody
would admit that the HDS is broken)

I got some more info on the history of international copyright laws.
Apparantly UNESCO is dealing with this, this is the forum that the
Berner Convention is discussed. Software protection has been discussed
here too, and during the 1970-ies they reached a concensus that
software should be protected thru copyright, as a litterary work.
The USA then made the new copyright act in 1980, and some bigger
European countries followed up, notably France and Germany (BRD) in 1985
included software explicitly in the coverage for copyright in their
revisions of copyright laws.

If you had your troubles in Germany before 1985, then it might have
been because German copyright laws did not cover software at
that time. I am no expert on German law, however.

>In other words: you can read and discuss laws and legalities all you want,
>but in the *real world* all this means very little.

I now presume that your experiences is pre-1985, and that German
law did not protect you. That must have been the reason why neither
the police nor your lawyers would help you.

If your product enjoys copyright protection and this is violated,
then this is what I understand the Danish law to be: The offence
is a criminal case, and the state attorney is taking your case,
you will not have to pay any lawyers expenses. The offender can get
sentenced to penalties or in worse cases ordinary imprisonment up
to 3 months. I think your case would be of the worse kind, as it
was for profit. The offended has to go to the police and make an
action on the offence.

Additionally you can claim damages, but this is a civil case.
Having the offender sentenced in the criminal case should make
it easier to get the damages thru in a civil case, though.

I have no experiences of my own on such cases, so your comment on the
real world and slow/uninterested police I cannot offer any real
background for. It is of cause always easier in the books and
and easier if you are near to the offence. It is my impression that
the police takes all criminal offences seriously, especially when
there is much money involved; the courts may be slow though.

I do think though that your German "experience" was caused by lack
of software protection at that time in German laws, and the
situation has improved considerably since then, the conditions for
foreign software producers in Europe are not as bad as you indicate.

> 1) make it work from gulaam (my copy of 2.x does not, or is it me?)
> works ok from desktop (old ROM, no blitter, 1040, HD)

I have no problem invoking Uniterm from Gulam, or Gulam from within
Uniterm. As a matter of fact, I used Uniterm to dial into work, an
then ran UW from Uniterm. (UW gives me multiple terminal windows).

> 2) ability to invoke arc or less (or any command for that matter)
> (maybe it does now...not being able to invoke from gulaam forced
> me back to v1.7b and i haven't really read new docs)

Again, not a problem.

> 3) would be nice to see file size/dates in fsel dialog (i.e. replace
> fsel with something better)

You're _really_ asking for an improvement in GEM. Simon Poole has
done us all a service by developing Uniterm, for little reward aside
from the personal satisfaction. It just doesn't seem reasonable to
complain about his using a standard part of the GEM user interface in
a standard way.

> otherwise i use uniterm almost exclusively on ST. it is really nice! all this
> from freeware...

I'll bet that if you take another crack at it, you can Uniterm to do
what you want.

I am curious about the horizontal and vertical blank interrupts. How much code can one safely put in a horizontal blank routine? How many micro seconds does each call of the default vertical blank handler take? There appears to be a flag telling the default vertical blank handler to cut its operation short: what awful thing (if any) would happen if the interrupt threshold was simply set above the vertical blank level? And finally, how do I try playing with these things (I've never done anything with privileged instructions on the 68000, so those interrupt levels and first 1 K of memory flags are new territory). I have Mark Williams C (with their assembler included), a few Abacus books and some 68000 documentation. Use your best judgement about whether to mail or post replies.

to a great extent, or at least a large extent, the manufacturer and OS
designer really should define the standard. Ok, now that im awake and realize
who am im talking about (atari corp./DRI) this is obviously asking far too
much.

first of all, atari has virtually no control over the OS: i don't even
think they have source to much of GEM/TOS/GEMDOS/... it's difficult even
to know the proper NAME of the OS and it's parts, let alone specific
details. atari was not remiss in leaving a fair amount of discression
up to developers and warned continously about using "non standard" or
reserved things (sys variables, etc.). this puts the onus on developers
to make sure versions of the OS do not effect their program's behavior.
this is fine for most programs that do little or no "outside" things
but not the case for programs relying on quasi-documented "features".
what atari could do is realize that certain programming really helps
refine their machine and try to accomodate the developers. they are,
however, really not set up to do that and instead choose to respond with
"ha, i told you so!".

you are naive to think that programmers will magically band together
and standardize the way things are done, especially those of us in it
for the $$$.

i really don't know how further standardization will give you any more
power. for all its problems , GEM ain't too bad.

>ST availability complaints around that I'd believe that Atari is promising
>but not shipping to everybody (doesn't sound like something they'd do...)

with the way atari is clamping down on retailers, and the fact that they
currently have NO SH204 hard drives in stock, i suspect the problems are
with atari and it's primary distribution chain and not the retailers.

MegaByte Computers (Webster TX) just told me yesterday that in general, you can expect 30 to 85% speedup. if the inner loop of a process is primarily calculations and not hits to the OS (like I/O, etc.) you get the higher numbers. they also say you can switch on-the-fly between 8 Mhz (normal) and 16 Mhz, even during a program execution! no reboot needed.

they are planning a board for the mega as well, though expected dates were not known. they plan to also have additional sockets for memory on that board, and perhaps a floating point coprocessor. if all this happens, the mega will turn into a rather formidable machine ($200 delta on the mega is probably worth the performance increase for all megas. you be the judge for ST).

This chain appears to carry the implication that Microsoft Write does *not* come with sufficient information to allow the purchaser to custom-brew a print driver appropriate for <whatever they've got>. Is this true? (If so, it's a major lack, in my (not very) humble opinion.) Comments?

>door while they were still warm on the coding pad.

David Beckemeyer's point is valid, of course. And, of course, it also applies to Atari. However, we've been hearing from Atari about the things they're going to fix for some time now. Over a year, in some cases. There thus seems to be reasonable cause to suspect that they have fallen, or are in danger of falling, into the mirror-image of this issue. To wit, the 'continual fiddling' syndrome -- I'm sure we all know programmers who suffer from it. (I certainly know some, and indeed I am aware that I personally am prone to it and so have to conciously avoid it.) You know the one, don't you? 'Well, I've fixed bugs A, B, and C, but in the process I realized that D could use a little bit of poking with, so I need another week...' And then, 'Well, while I was poking D, I noticed that E is a bit suboptimal...' And so on. There does come a time when you've got to bite the bullet, freeze a version, and get it out the door -- resigning yourself to the fact that you're NOT going to be able to find and fix everything.

Of course, Mark Williams have a bit of an edge, as they are dealing in software (discs) rather than hardware (ROMs) -- but even so...

Remember, there is a wonderful replacement file selector called the "Universal File Selector". You simply put in in the AUTO folder and forget about it. It adds a click-on drive selector plus Format, Create Folder, Move, Copy, Rename, Delete, Disk Info, Print Directory, Protect and Unprotect. It is well worth it's outrageous price of $15 - I suggest you check it out.

2360. Migraph postpones PS...

Newsgroup: comp.sys.atari.st
Date: 1988-03-09 13:05:00 UTC
From: FXDDR@ALASKA.BITNET
Message-ID: <8803092058.AA27373@ucbvax.Berkeley.EDU>
Source record: 253910

Of course not long after asking if anybody had heard about Migraph postponing the PostScript driver for EasyDraw, along comes the first Migraph newsletter in months, called "HEADLINES". In it:
Q: Where are your Postscript and color printer drivers?
A: We are working our buns off at Migraph and there always seems to be some project taking priority over others. All I can say is we all hope to have them available in the first half of 88.
Anyway I'm playing with Axel's excellent MFPS program so I don't know if I'll need Migraph's driver (maybe somebody at Migraph saw MFPS and felt theirs was superfluous). I hadn't known that he had a Unix version of MFPS, and running it on the Vax which has the PS printer makes a lot more sense than doing it on the ST and transferring huge PS files to Vax.

The newsletter might interest non-EasyDraw users. It was produced on the (in)famous Atari laser printer (though of course mass-produced by another process). And, page 6 was produced with the new Deskjet printer. Seeing the two types of output side by side there just isn't a whole lot of difference. Don't know if the mass production improved or degraded the quality of the originals, but they both look very good. Migraph is pushing the Deskjet themselves for $949, including GDOS drivers.
Since Migraph has GDOS drivers for HP Laserjet and now the Deskjet, that would seem to eliminate the only real argument for the Atari laser printer ("GDOS is available for the Atari laser, will any of the cheaper ones have support"). And: "The Deskjet gives you beautiful full-page 300 dpi graphics without needing additional memory (you can hook it up to a 1Mb ST)." Same is true for many of the < $1500 lasers. So I don't see that the Atari laser has a future...
What would be very useful for the bitmapped lasers would be an interface to the ST DMA port so 300 dpi images could be loaded into the printer in a minute or two instead of the 10+ minutes it takes to load the HP Laserjet via the parallel port.

Actually, Uniterm 1.8 has that particular option (if memory serves). You can run your favorite text editor while still conected to a BBS, for example, and then upload the file. I've even used that particular feature to scan through some ARC files for a piece of relevant information I want to upload. In the FILE menu is the option "Run Program". It works quite nicely ... although you will have to set up your buffer space so that you have enough space to run a particular program. On a 1040ST, a system buffer size of 200K is not bad.

In 2.0 you can even set things up so that a single keypress (like F1, etc.) automagically invokes your text editor this way. The Macro capability in Uniterm is becoming very, very useful. You can even set up an equivalent to the DO files of Flash...

The program is legitimate. There has been a virus located and dissected in Europe. I first heard about it a month ago, when I got the back issues of an informational disk called ST NEWS from Richard Karsmakers from The Netherlands. He was *quite* furious when the virus was discovered.

I haven't personally looked at the program on CANADA01, but I *do* have all copies of ST NEWS relative to the virus, its detection and quashing. If you'd like to see a copy of ST NEWS and read about the whole thing yourself, you can send me a disk and return postage (or two disks for the last two issues). I wrote to ST NEWS and now I [and our local user group, MAST] will be distributing the disk in the U.S.

I can't write much more about the subject, since I haven't paid all that much attention till mid-February. The 'details' are on the disk. The VDU program was, I believe, written in GFA BASIC.

If you want to see the issues discussing the virus, send a disk (or two) and enough postage to get them back to you to:

Dave Meile
Box 13038
Minneapolis, MN 55414

Future (and back) issues will be handled via MAST. Look for an announcement.

[...]
>#D function most likely stands for DIRECTORY not DISK while the first
>#F probably stands for FILE rather than FOLDER. Based on what I say
>for the rest of the examples maybe someone can figure out what these
>first two lines do.

I was right about #D for DIRECTORY. But I not sure what useful tricks
you can do with it.

eg. #D 01 01 GAMES@ *.*@ - Seems to allow you only to look at the
GAMES directory, while clicking on any other directory cause a warm
boot.

eg #D 01 04 GAMES@ *.PRG@ - Seems to bomb (2) when you click on a file
in that directory.

>eg. #G 03 04 GEMCSH.PRG@ *.SH@ - When any .SH file is opened, execute
>GEMCSH.PRG passing the specified file name on the command line.

Can be done with TOS and TTP files as well. Also it is possible to
install more than one file for an application. But you can't do this
from the desktop options.

eg. #F 03 04 LV.TOS@ *.C@
#F 03 04 LV.TOS@ *.H@ - Clicking on either a .C or .H file will
execute LV.TOS with the given file.

>So from the above I can only speculate to the following meanings as
>I have not tried them.
>
>eg. #F FF 04 @ *.*@ - What constitutes a none executable, displayable
>file.
>
>eg. #F FF 04 @ *.DOC@ - This to me means that I can "show" any file
>with a .DOC extension.

This one was right. Any other file simply caused a reboot as the system
did not know what to do with it if it was not mark for execution or
display.

>eg. #D FF 01 @ *.*@ - What files should be listed when a folder is
>opened.

Wrong. Still don't know what this spec means.
